## PREFACE.

---

This volume—the eighteenth of the series—contains an account of the astronomical observations for latitude, which have been taken at stations of the principal triangulation of India during the last twenty years. The observations which were taken prior to 1885 have been already described in Volume XI of the *Account of the Operations of the Great Trigonometrical Survey of India*, and Volume XVIII may be regarded as the continuation of Volume XI.

In Part I of the present volume the methods of observing and computing are described; in Part II the values of latitude are deduced from the observations; in Part III the results of Part II are combined with those of Volume XI.

Part III thus contains complete classifications to date of all latitude observations taken in India, and of the resulting deflections of the plumb-line in the meridian.

In Appendix No. 5 are shown the deflections of the plumb-line *in the prime vertical* as deduced by Laplace's equation from azimuth observations. In the present volume there are therefore compiled the results of all determinations made in India of the direction of gravity with the exception of those few which emanate from the longitude operations and which have been described by Colonel George Strahan in Volume XV.

### *The standard of accuracy desirable in latitude observations.*

The question has been raised of recent years whether astronomical latitudes are not observed with unnecessary accuracy. Differences of 6" and 8" between the astronomical and geodetic values of latitude are of frequent occurrence in all parts of India, and in discussions of deflections of the plumb-line the quantities involved are so large as to render the inclusion of decimals a superfluous refinement. On the other hand our astronomical latitudes are observed with so much care, that the probable error of a result seldom exceeds 0".06. Would it not be better, it has been asked, to devote less time to one station and to increase the number of stations? Similar controversies over the accuracy necessary in triangulation and in levelling have taken place at intervals and will recur in the future.

There are two objections to lowering a standard of accuracy: the first is that we cannot foresee the purposes which our observed latitudes will be required to serve when the geodetic problems confronting our generation have been replaced by others: the second is that probable errors, though useful for purposes of comparison and combination, are not sufficiently reliable criteria to be accepted as absolute measures of accuracy.

When we say that the *probable* error of a latitude is 0".05, we know that the *actual* error may be 0".20 or more: when we calculate that the probable displacement of the terminal station of a chain of triangles is 10 feet, we cannot forget that the actual displacement may be 40 feet or more.

To make use of the law of probability in estimating the weight of a result is a course generally recognised: but to base the design of a geodetic operation upon this law would be incorrect unless we could prove that the operation was not liable to systematic errors or mistakes. Our triangulation, our levelling, our tidal, pendulum and astronomical observations have all in turn exhibited signs of systematic error; and our best observers have been liable to make mistakes. When therefore we prolong and multiply observations at any one station, and when we introduce different conditions into work, we have in view not a decrease of the probable error, but a cancelment of the evil effects of systematic errors and an elimination of all possibility of mistakes.

Let us suppose that we now consented to accept a lower standard of accuracy in triangulation and astronomical work; we should know that we were breaking the uniformity of the survey and we should commence to accumulate

results which, though possibly of present use, might be found defective in the near future, when our knowledge of the form of the geoid, and of the variation of latitude, and of the constitution of the earth has advanced. And what should we gain in return for these disadvantages and risks? We are promised more latitude stations and a speedier and cheaper triangulation. It is doubtful however if these promises would be fulfilled. The time and trouble that an observer takes in getting his instrument and himself to an observing station in the field are so great, and the necessary preparations for work are so many, that when everything is once in working order at a field station it is the wisest and most economical course to repeat observations under different conditions and thus to guard against all possibility of grave error.

The triangulator by increasing the lengths of his rays, the areas of his polygons and the dimensions of his circuits, can provide a fundamental network of principal triangles as cheaply and rapidly as one of secondary. Where principal triangulation is slow and dear, there will secondary and tertiary triangulation be slow and dear also, and nothing will be gained by reducing the accuracy of the foundation. We are only concerned in this volume with astronomical work: I have introduced the subject of triangulation to show that we are not now discussing a narrow question which concerns latitude observations only, but that the accuracy of all geodetic operations is involved.

For the last 30 years a latitude observer has been expected to show at the end of a season's work a mean probable error of  $0''.06$ , and it is considered undesirable to introduce a change now. Many of the probable errors of the results tabulated in this volume will be found to exceed  $\pm 0''.06$ , but in every such case the circumstances were exceptional: at times observations have been unavoidably curtailed because of the unhealthiness of the district, at times through the failure of supplies, and at times on account of the persistence of clouds.

Many probable errors in the volume will be found *less* than  $\pm 0''.05$ , and what is of more importance the continued efforts of Major Lenox Conyngham, Captain Tandy and Captain Cowie have largely tended of recent years to free our latitude results from the effects of constant error.

### *On the adopted value of latitude for the station of origin.*

The deflection of the plumb-line in the meridian at any station is obtained from a comparison of the observed value of latitude with the value calculated from the triangulation. The latter value is liable to be in error, firstly, because the computations of the triangulation are based upon an assumed figure of the earth, and, secondly, because the position on the globe of the whole of the triangulation is dependent upon adopted values of the latitude and azimuth of the station of origin. The first difficulty can be temporarily surmounted by exhibiting deflections of the plumb-line on different spheroids: the second difficulty admits of no easy solution.

The latitude of Kaliánpur has been observed many times during the last century; throughout this period our knowledge of the places of the stars has been continually increasing, and our instruments have been repeatedly improved; our more recent observations of this latitude deserve therefore greater weight than those of our early predecessors.

In Chapter IV of this volume it is shown that the general mean of all observed results is  $24^{\circ} 7' 10''.97$ , and this is the value that we should adopt for the latitude of Kaliánpur, if we were free now to make a determination. But we are not free: we cannot cut ourselves adrift from the past: this volume is one of a series, in which we have to preserve continuity. The work of our generation is but the link of a chain, and we have to see that our link is connected with that of our predecessors. In this volume I have therefore adopted Everest's original value for the latitude of Kaliánpur, viz.

**$24^{\circ} 7' 11''.26.$**

This value has been adopted because all the computations of geodetic latitude, that have been made in the preceding volumes of this series, and all the results that have been published in those volumes have been derived from Everest's original value. I do not contend that our successors will be bound for ever to continue this value, but *the time for change has not come yet.*

It is worthy of notice in this connection that within the last year the committee appointed in 1904 have recommended to the Government of India, that the old Indian value of longitude still employed upon our maps should be abandoned, and that a more correct value should be introduced.\* The old value has however been used throughout our principal triangulation and we have had to consider what steps ought to be taken in consequence to maintain the trigonometrical survey abreast of the topographical: no immediate step has been rendered necessary, because for the present

\* See the preface of Vol. XVII of this series, which contains a note on the values of longitude employed in Indian mapping.

the shift in longitude is to be confined to published maps and is not to be introduced into triangulation. This course is however recognised to be a tentative measure, and it may have to be supplemented shortly by more radical changes.

Though no great revision of data has been suggested until now, further revisions will be inevitable in the future, and so I take this opportunity of explaining the course which I think we ought to pursue.

### *Revisions of trigonometrical data.*

We have known for years that errors pervade our geodetic and geographical data.

- ( i . ) The longitudes of all stations of the triangulation are in error by about  $2' 27''$ ;
- ( ii . ) The latitudes of these stations are in error by about  $6''$ ;
- ( iii . ) Superposed on the above errors are further considerable errors due to our adoption of Everest's spheroid;
- ( iv . ) The Standard foot for India differs from that of England;
- ( v . ) An artificial value was introduced for the fundamental azimuth of the triangulation (see Appendix No. 5 to this volume);
- ( vi . ) The closing errors of the circuits of the triangulation were adjusted without consideration of the azimuthal errors revealed by Laplace's equations (See Appendix No. 5);
- ( vii . ) The great triangulation of Burma has remained to this day in terms of the Sonákhoda Base-line and of an observed azimuth at Madhupur—terms that are different to those adopted for the triangulation of India;
- ( viii . ) The closing errors of the levelling circuits have not yet been adjusted;
- ( ix . ) The expansion of levelling will necessitate a reconsideration of our trigonometrical values of height.

A perusal of the above list will show the formidable tasks that face our small computing office: extensive recalculations and republications will assuredly be necessary.

On the *geodetic* side of the office the compilation of a volume dealing with the Levelling operations has lately been put in hand, and another volume which will contain details of the Burma triangulation is contemplated: further volumes to deal with the Pendulum, Magnetic, and Tidal operations are in prospect.

On the *geographic* side of the office a volume is being compiled in which the positions and heights of the observed peaks of the Himalayas are being recorded and classified; complete lists are also being prepared of all peaks observed in Tibet and Afghanistan; and the adjustment of the levelling errors will necessitate the withdrawal and republication of our numerous pamphlets on bench-marks.

Frequent revisions of data are undesirable\*: it is better to continue with incorrect data than to introduce confusion by constant changes. When moreover several sources of error exist, an attempt should be made to eliminate all simultaneously and with this object in view postponements of intermediate revisions are often justifiable.

From the geodetic point of view the time is not yet ripe for revision: the effects of local attraction on our observed values of latitude, longitude and azimuth at Káliánpur are still uncertain; the investigation of the movement of the pole is in its infancy, and no method of correcting observed astronomical results for periodical variations has as yet been devised. It would be premature to reject the spheroid of Everest, until a new spheroid has been definitely recommended by the International Geodetic Association. It would be premature to adjust the errors of the levelling circuits before the level net for India has been completed, and before the questionable line between Bombay and Madras has been re-observed; and it would be premature to publish new values of latitude, longitude, side and azimuth for the triangulation of Burma, when it is confidently expected that base-lines will be measured within a few years.

The *present* task in front of our computing office is rather to *make ready* for the inevitable revisions of geodetic work than to publish revised values immediately. It is important to make ready—to carry through all the preliminary steps, and to have a definite plan in view. It will throw undue work on our successors, if we fail to maintain,

---

\* See Chapter II of this volume. See also General Report of the Survey of India for 1903-04, page xxvii.

unpublished data both up to date and on one uniform system, and if the necessary preliminary steps to revision are not taken as soon as they become possible.

The results of our *geodetic* work have been published in a series of professional volumes of which this is the eighteenth. When the time comes for revising those results, we ought to devote a new and entire volume to the revision. The early volumes of this series have already attained an historic value, and it would be out of the question for us to cancel the works of our predecessors, or to publish revised editions of those works. Every geodetic survey has had its history, and has—especially if it were a pioneer—fallen into mistakes. It is not for us to obliterate all mention of those mistakes under the cover of new editions: the only safe course to pursue is to leave the published volumes unaltered, to recognise the mistakes committed, and to publish periodically a new volume of the series, in which the results of preceding volumes are brought up to date.

Such a volume would explain our reasons for abandoning the spheroid accepted in Volume II, for correcting the geodetic co-ordinates given in Volumes III, IV, IVA, V, VI, VII, VIII, XII, XIII and XIV, and for modifying the deflections of the plumb-line of Volumes IX, X, XI and XV. Just as we have to revise the results of the past, so will our results have to be revised in the future; and the periodical publication of occasional additional volumes of this series will do for the geodetic survey what periodical revisions of maps in the field do for the topographical survey.

But although we are not called upon to revise our geodetic data immediately, we must recognise that the adoption of a new value of longitude for our published maps may oblige us shortly to revise our geographical data. It will be no doubt troublesome at first to have geodetic and geographic data differing from one another, but we cannot expect the topographical survey to wait for the geodetic errors to be eliminated.

Our geographic results are published in series of synoptical volumes and levelling pamphlets, in which the positions and heights of stations in India are recorded: these volumes and pamphlets, containing as they do mere numerical data for surveyors, may be cancelled and revised over and over again. The change that has been now introduced in the longitude of maps may necessitate the early revision of all our synoptical volumes; the simultaneous reduction of the levelling net will render all our spirit levelling pamphlets obsolete.

### *The Earthquake of 1905.*

In connection with the subject of revision the effects of earthquakes upon the positions of trigonometrical stations will have to be periodically considered. On April 4th 1905 Mussooree and Dehra Dún were severely shaken by the great earthquake, which wrecked Dharmasála and Kángra. The standard clock and the turret clock of the Survey office at Dehra Dún were stopped by the convulsion, and the office itself was damaged. It appeared possible to those of us who witnessed the catastrophe that the positions and heights of the surrounding stations of the Great Arc series of triangulation might have been affected, and steps were taken to ascertain the extent of the displacements.\* Several horizontal angles of the principal triangles at the northern end of the Great Arc of India were re-observed; owing partly to the haze the revisionary observations were not of the highest order of accuracy, and we were consequently unable to discover whether horizontal movements of six inches or less had taken place or not: a comparison of the results however showed (1stly) that no relative horizontal displacement of 8 inches had probably occurred near Dehra Dún, and (2ndly) that no relative horizontal displacement of 12 inches could have occurred.

Our revisionary work was necessarily local, and we had to be content with determining the extent of relative displacement within the locality tested. It would not have been possible without great expense to discover whether there had been any general movement of the Himalayas.

There have been erected in India 3706 trigonometrical stations of the principal triangulation: in 1904 there were 3515 surviving. In spite of measures taken to ensure preservation the average rate of decrease has been of late about 4 stations per annum. The rivers of northern India by their constant changes of course have been very destructive; encroachments of the sea have washed stations away, the expansion of railways, canals and towns have necessitated the removal of others and movements of sand in the desert have caused a few to be buried. It is not possible to state the number of stations which have been displaced by earthquakes from their original positions, but seeing that severe earthquakes have only occurred of late years in certain sub-Himalayan regions and having regard to the recent reassuring observations round Dehra Dún, I do not think it probable that the number which have suffered greater disturbance than 6 inches can exceed 40: and an estimate of 40 errs on the side of pessimism.

---

\* An account of the steps taken was included in a report on Geodesy submitted to the Board of Scientific Advice, in November 1908, and subsequently published by the Board.

After the great earthquake of 1897 we discovered horizontal displacements in Assam of 8 feet and more.\* Mr. Oldham was of opinion that these were merely relative displacements in the small area tested and that the absolute displacement of the whole area would have been found to be considerable, if we had commenced our tests outside the disturbed region and worked inwards to the epicentre. But triangulation is a slow and costly operation, and it is not practicable to revise great lengths of it after every earthquake. The small local revisions carried out last summer to test the effects of the earthquake of 1905 were rendered possible by the fact that Dehra Dún is the head-quarters of the trigonometrical survey and observations can be taken in its vicinity without expense or difficulty. The damage, however, done at Dehra Dún by the earthquake was small compared to that at Dharmsála, and our proof that the stations round Dehra Dún have not been relatively displaced by six inches is no proof that those near Dharmsála have remained equally undisturbed. If moreover we apply Mr. Oldham's argument to the case of Dehra Dún, we shall have to consider that the whole region may possibly have moved, although the relative positions of local marks have remained unaltered.

From a topographical point of view a displacement of 6 inches may be disregarded, but one of 10 feet is liable to cause inconvenience and error. If we suppose for instance that of the two trigonometrical stations of Hátidhár and Lipiána which are situated in Kángra 16 miles apart, one has been displaced *towards* the other by 10 feet, then the line joining the two would no longer form a suitable base either for the observation of distant snow-peaks, or for a series of minor triangulation for Tibet, although the disturbance might not embarrass plane-tablers surveying the immediate locality. If the displacement had occurred in a direction *perpendicular* to the line joining the two stations, the accepted azimuth of this line would be in error by 25", and this is an error that would soon begin to inconvenience triangulators.

The Shillong earthquake of 1897 rendered the positions of perhaps 15 stations uncertain, and the Dharmsála earthquake of 1905 has possibly affected the same number. When in the future these stations come to be utilised, it will be necessary for observers to take the precaution of measuring the angles of two or three of the original triangles by way of a preliminary test.

We have long since had to introduce such a precaution into levelling operations: the heights of bench-marks when erected on alluvium are liable to vary with age, and when a new line of levels is being started from an old bench-mark it is not safe to accept the original value of its height: it is always necessary to relevel to two or three of the old bench-marks in order to test for subsidence. Such a precaution has never hitherto been considered necessary in triangulation, because, although markstones may move vertically in the course of time, as a rule they maintain their horizontal positions. But there have been two severe earthquakes within eight years, and it is necessary now to recognise that in certain regions the positions of points will have to be accepted with a greater caution in the future than in the past.

The displacement of the stations of the principal triangulation is but one aspect of the general problem of change which a survey has to face. The forms and positions of topographical features are always undergoing change. In certain cases the changes are so rapid that it is hardly possible to make a consistent survey at all: the Indus, for instance, is constantly eroding its banks, washing away survey and boundary marks, and altering its course perhaps by a mile or more. If the whole river were to be surveyed in one month, the map could be rightly headed "The course of the river Indus in January 1905", but to survey different portions at different times, as in practice we have to do, is to give a course to the river, which it never actually pursued.

During the progress of the present survey of Sind, many recently surveyed sheets have been rendered obsolete almost before they have been published by the opening of a new system of canals. And these changes are going on everywhere, varying in character from those that are so local and marked as to be perceptible to the most casual observer, to those that are so wide-spread and gradual as to require lengthy revisions of triangulation to reveal them.

A line of spirit-levelling had been run in May 1904 from Dehra to Mussooree, and had given a difference of height of 4706 feet 10 inches. Owing to the earthquake this line of levels was revised in May 1905, when the difference of height was given as 4706 feet 4½ inches. It therefore appeared that the Mussooree range had subsided 5½ inches with regard to Dehra Dún.

When the revisionary results were first tabulated, it was perceived that the amount of the subsidence increased gradually as the levellers ascended the range. This gave rise to a suspicion that the lengths of the levelling staves may have been in error. During the first 6 miles, the ascent is 694 feet or 116 feet per mile, and in the last 12 miles it is 4013 feet, or 334 feet per mile. A levelling staff being 10 feet long, and the difference of height being 4707 feet, there were contained in the total rise 471 lengths of staff. If then the 10-foot staves had been 0·001 foot too long, our unit of measurement would have been slightly in error, our measured heights would all have been given too small and the deficiency accumulated at Mussooree would have been 0·471 of a foot or about 5½ inches.

Four different staves are however in daily use, and these are periodically compared in the field against a 10-foot steel standard and corrections for each deduced. An examination of the results of the comparisons showed that the apparent subsidence of Mussooree could not be attributed to errors in the adopted lengths of the four staves.

---

\* The revisions in Assam were made with a small instrument and the displacements were measured to the nearest 2 feet only: *vide* Report on the Trigonometrical Results of the Earthquake in Assam, 1898, para 7.

The steel standard against which they were compared was then suspected, and this was subjected to rigorous tests under comparing microscopes at Dehra Dún. Its length, as determined, accorded with the value previously obtained, and it became clear that the observed change in the height of Mussooree above Dehra Dún between 1904 and 1905 could not be attributed to any error in the adopted length of the standard of reference.

During the process of levelling the level is always erected midway between two staves, and at each station the observer by reading the staves through the telescope deduces the *difference* in height between the two points on which the staves are standing. Under ordinary circumstances there is no reason to fear accumulation of error. But when the line followed is constantly rising, as between Dehra Dún and Mussooree, the ray from the telescope to the higher staff is always nearer the ground and more likely to be disturbed by radiation than the ray to the lower staff: this fact introduces an uncertainty, which continues to exist whether we work up or down the hill and which we endeavour to minimise by stopping work during the heat of the day.

We are not, it is true, discussing now the absolute value of the height of Mussooree: the levelling observations of both 1904 and 1905 were taken in the month of May under similar atmospheric conditions, and we are only attempting to account for the *difference* of  $5\frac{1}{2}$  inches which appeared between the value obtained in May 1904 and that of May 1905. Nevertheless it has to be recognised that an uncertainty does exist: it was the examination of this question that really revealed how little was known of the degree of accuracy of a line of levels on a steep slope. It is at times extremely difficult to obtain a definite numerical idea of the probable and possible errors which are accumulating in a lengthy survey operation, but a knowledge of these errors is essential before we can discuss the meaning of an actual discrepancy observed. In the levelling operations carried over the plains and peninsula of India, no error approaching  $5\frac{1}{2}$  inches in 18 miles has been met with.\*

Owing to the doubts that were felt, the levelling operations between Dehra Dún and Mussooree were repeated for the third time in October 1905; the difference of height was now given as 4706 feet  $5\frac{1}{2}$  inches. Although then there is some evidence in favour of the view, that the earthquake decreased the difference in height between Dehra Dún and Mussooree by 4 or 5 inches, I do not consider that we are justified in stating that such a decrease has been actually demonstrated.

### *Investigations of Himalayan Attraction.*

Within the last five years attempts have been made at Dehra Dún to investigate the subject of Himalayan Attraction. In 1901 a paper was published in the Survey of India professional series on this subject, in which it was shown that the deflections of gravity from the vertical could be broadly classified by regions, and that though the deflection within any particular region might remain constant throughout a wide area, yet it might differ considerably from the mean deflection observed in a contiguous region. The regional classification led to the conclusion that a long chain of excessive density lay buried in the earth's crust between Balasore and Jodhpore.

In a subsequent paper prepared for the Royal Society I was able by the aid of Professor Helmert's graphical interpretation of the old Indian pendulum results to show that these latter confirmed the conclusions that had been previously arrived at from a consideration of deflections of the plumb-line only. Observations taken since 1902 have tended also to confirm the view that along the northern border of the Ganges valley the earth's crust is deficient in density, that the density increases towards the south, and that a buried chain of excessive density runs parallel to the Himalaya along the southern border of the Gangetic plain†.

It is perhaps advisable for me to explain why the subject of Himalayan attraction has received so little notice in this volume. These volumes are designed to record facts for the permanent use of geodesists: they are not intended to be contributions to contemporary discussion or to include speculations, which will be sooner or later rendered obsolete by new discoveries and advances. Contemporary discussion is necessary for the determination of programmes: without it work degenerates into routine, its aims get lost sight of, and the accumulation of observations rather than their meaning becomes the main object in view: but these volumes are intended for the classification of data and not for the record of arguments and hypotheses.

Nothing has tended more to further the progress of geodesy than the institution of an international association under which the several geodetic surveys of the world now co-operate. The geodetic survey of India has profited of late in many ways through its connection with the international association. We have been able to refer questions of difficulty to Professor Sir George Darwin, K.C.B., the representative of Great Britain, and we have derived very great benefit from the advice and help of Professor Helmert, the director of the association. The reports of the international conferences have been found useful and instructive guides.

\* The great error of 3 feet between Bombay and Madras may have been partly generated in the steep ascent of the Gháts on the Bombay-Poona section, but the weight of the evidence is against this view.

† The term "excessive" is relative: it may hereafter be found that density is nowhere in *absolute* excess. The gradual increase in density from north to south has the appearance and effect of a hidden trough on the north and a hidden chain on the south. *Philosophical Transactions of the Royal Society of London, Series A., Vol. 205, 1905. On the Intensity and Direction of the Force of Gravity in India.*

In the winter of 1905 Doctor Hecker who had been deputed by the Royal Geodetic Institute of Potsdam to observe the intensity of gravity over the great oceans, visited India in the course of his tour of the world, and joined Major Lenox Conyngham's pendulum party in camp in northern Bengal. For three days and nights the two observers worked together, and obtained independent values of the times of vibration with their respective pendulums. Their co-operation will enable Major Lenox Conyngham's results to be standardised in terms of the absolute value of gravity at Potsdam. Doctor Hecker afterwards visited Dehra Dún, where he took magnetic observations with his own instruments in the magnetic observatory of the survey office.

This volume was printed at the office of the trigonometrical survey in Dehra Dún under the supervision of Mr. J. Eccles, M.A., and of Lieut. C. M. Browne, D.S.O., R.E., who officiated for Mr. Eccles during the latter's absence on furlough: to both officers I am much indebted for their constant and valued assistance. Mr. Eccles was formerly one of the latitude observers, and he took an important part in the preparation of Vol. XI; I have derived great benefit from his experience.

The historical and descriptive chapters were compiled in the first instance from the records of the survey by Lieut. R. H. Phillimore, R.E., to whom my acknowledgments are due for the care he took to render the accounts accurate and complete.

The numerical data were abstracted and tabulated by Babu Kartar Singh and Babu Baldeo Behari Lal of the Astronomical party, and the printing was carried out under Babu Sarat Kumar Mukerji, to all of whom I express my obligations for the interest they have shown in the work.

The formulæ and results have been checked throughout by Babu Shivrath Saha, the head computer, by whom also I was very materially assisted in the calculations for Appendix No. 5.

The final proofs for the volume were scrutinised by Babu Ishan Chandra Dev, B.A. and Babu Ganga Prasad Mathur, who have introduced many improvements and detected in time not a few mistakes.

By the courtesy of the Rev. Osmond Fisher I have been able to publish as Appendix No. 1 his contribution on *Deflections of the plumb-line in India*: it is many years since Mr. Fisher first showed his interest in the geodetic work of India in his well-known book on mathematical geology, "*Physics of the earth's crust*", and I have been much gratified at being able to include in a volume of the survey a paper by this distinguished investigator.

Captain Cowie, who has carried out many investigations of the value of the micrometer screw of the zenith telescope with equal skill and patience, kindly wrote for me both the chapter and appendix that deal with the micrometer value: his determination of the periodic errors of the micrometer screw is in progress but is not yet complete. Captain Cowie also contributed Appendix No. 2 and initiated the system, under which the latitude results have been abstracted from the original records. Major Lenox Conyngham has kindly examined every proof, and the value of the volume has been much enhanced by his corrections, additions and suggestions.

**HISTORY.—DESCRIPTIONS OF THE INSTRUMENTS, OF THE  
SYSTEMS OF OBSERVING, AND OF THE METHODS OF  
REDUCING THE OBSERVATIONS.**

## CHAPTER I.

### INTRODUCTORY.

#### 1.

##### *The observations described in Vol. XI.*

The astronomical observations, which were taken in India prior to 1886, for the determination of the latitudes of a certain proportion of the stations of the Principal Triangulation, have been discussed in Vol. XI of the *Account of the Operations of the Great Trigonometrical Survey of India*. The observations for latitude, with which the present volume deals, were made in continuation of those described in Vol. XI. The present volume—the eighteenth—resumes the subject at the point, where Vol. XI left it, and carries the description and discussion of the observations down to 1905.

From the year 1872 to 1884 the determination of astronomical latitudes was in abeyance owing to the fact that both astronomical parties were engaged on the determination of differential longitudes by electro-telegraphic signals.

In 1884-85, as two officers were not available for longitude operations, Lieut.-Colonel Heaviside recommenced latitude work in northern India on the meridian of  $80^{\circ}$ : the observations taken during that season were the last with which Vol. XI dealt.

#### 2.

##### *The observations, which have been taken since Vol. XI was written.*

The present volume treats of the latitude observations which were taken between November 1886 and March 1905; during that period latitude work suffered several interruptions, which are explained in the following table:—

Operations undertaken by the astronomical observers between 1885 and 1905.			
Seasons.*	Operations.	Observers.	Locale.
1885-86	Longitude	G. Strahan W. J. Heaviside S. G. Burrard	Punjab.
1886-87	Latitude	S. G. Burrard	Meridian of $80^{\circ}$ , southwards from the point, where Heaviside closed in 1885.
1887-88	Longitude	G. Strahan W. J. Heaviside	South India.

\* Owing to climatic conditions in India field work cannot be undertaken during the summer; as a rule observations begin annually in October and are continued through the winter till May. It is therefore convenient to refer to them by seasons and not by years. A season denotes the period during which the observers are at work in the field.

Operations undertaken by the astronomical observers between 1885 and 1905.—*contd.*

Seasons.	Operations.	Observers.	Locale.
1888-89	Latitude	J. Eccles	Meridian of $80^{\circ}$ , southwards from the point, where Burrard closed in 1887.
1889-90	Longitude	S. G. Burrard G. P. Lenox Conyngham	Central India.
1890-91	Latitude	G. P. Lenox Conyngham	Meridian of $80^{\circ}$ , from the point, where Eccles closed in 1889, to the coast line at Madras.
1891-92	Longitude	S. G. Burrard G. P. Lenox Conyngham	Eastern India.
1892-93	Latitude	S. G. Burrard	Meridian of $72^{\circ}$ from latitude $23^{\circ}$ to latitude $27^{\circ}$ .
	Latitude	G. P. Lenox Conyngham	Parallel of $18^{\circ}$ from west coast to Longitude $77^{\circ}$ .
1893-94	Latitude	S. G. Burrard	Meridian of $72^{\circ}$ from latitude $27^{\circ}$ to latitude $31^{\circ}$
	Latitude	G. P. Lenox Conyngham	Parallel of $18^{\circ}$ from longitude $77^{\circ}$ to East Coast.
1894-95 1895-96	Longitude	S. G. Burrard G. P. Lenox Conyngham	Persia and Europe*
1896-97	Latitude	S. G. Burrard	Madras Observatory.
1897-98	Latitude	G. P. Lenox Conyngham	Group round Agra.
1898-99	Latitude and Azimuth	G. P. Lenox Conyngham	A great group round Kaliánpur.
	Latitude	E. A. Tandy	East Coast of India.
1899-1900	Latitude	G. P. Lenox Conyngham	Ganges Valley, Meridian of $78^{\circ}$ .
	Latitude	E. A. Tandy	Meridian of $82^{\circ}$ .
1900-01	Experiments with Jäderin Base apparatus	G. P. Lenox Conyngham	Dehra Dún.
	Latitude	H. McC. Cowie	Western India on Parallel of $23^{\circ}$ .
1901-02	Latitude	H. McC. Cowie	Ganges Valley, Meridian of $88^{\circ}$ .

\* Volume XVII, *Account of the Operations of the Great Trigonometrical Survey of India*; also *Report on the recent determination of the Longitude of Madras* published at Calcutta in 1897.

Operations undertaken by the astronomical observers between 1885 and 1905.— <i>contd.</i>			
Season.	Operations.	Observers.	Locale.
1902-03	Latitude	H. McC. Cowie	Ganges Valley, Meridian of 79°.
1903-04	Pendulum	G. P. Lenox Conyngham	Dehra Dún and Coast Stations.
	Latitude	H. McC. Cowie	Himalayas, Meridian of 77°.
	Latitude	H. Wood	Nepal.
1904-05	Pendulum	G. P. Lenox Conyngham	Ganges Valley, Meridian of 88°.
	Latitude	H. McC. Cowie	Lower Burma.

During the five seasons 1892-93, 1893-94, 1898-99, 1899-1900, and 1903-04 two astronomical observers were employed on latitude observations: during the nine seasons 1886-87, 1888-89, 1890-91, 1896-97, 1897-98, 1900-01, 1901-02, 1902-03, and 1904-05 one observer was so employed: throughout the six seasons 1885-86, 1887-88, 1889-90, 1891-92, 1894-95, and 1895-96 the latitude work remained in abeyance.

*Season 1886-87.*

*Latitude Stations visited.*—*Sarey Khan (formerly known as Sarandi Pat), Lingmára, Sítúpár, Bhímsain, Rájuli.*

The operations carried out this season on the Jubbulpore Meridional Series formed part of Mr. Hennessey's scheme, under which latitude observations were to be taken along the meridian of 80° at stations half a degree apart from the Himalayas to the Madras Coast. In laying down this programme Mr. Hennessey halved the distance that had hitherto been considered desirable between latitude stations.

In 1884-85 Colonel Heaviside had commenced this series of observations in the north of India, and had worked southwards across the Ganges Valley: in 1886-87 Lieut. Burrard, R.E., crossed the Central Provinces from north to south and extended the series from the valley of the Nerbudda to that of the Godáviri. Burrard observed with Strange's Zenith Sector No. 2, and adhered to the methods and procedure formulated by Colonels Herschel, Campbell and Heaviside. A full season's work was not completed owing to the recall in March of the observer to Dehra Dún, where a series of experiments had to be undertaken with the transit instruments for the purpose of investigating the cause of the large circuit errors that had appeared in the longitude work of the previous season.\*

*Season 1888-89.*

*Latitude Stations visited.*—*Díwai, Ankora, Burgpaili, Rámگیر, Bolíkonda, Nídlamari, Dhúlipalla.*

In 1888-89 Mr. J. Eccles, M.A., extended the series still further south across the rivers Godáviri and Kistna into the Madras Presidency. He observed with Strange's Zenith Sector No. 2; whilst adhering generally to the methods of his predecessors, he increased the number of observations per station, and obtained very complete results.

\* Volume XV, *Account of the Operations of the Great Trigonometrical Survey of India*, pp. 373 to 387; also *General Report on the Operations of the Survey of India Department for 1889-90*, pp. 6, 70-72, iii to xi.

*Season 1890-91.*

*Latitude Stations visited.*—*St. Thomas's Mount, Madras Observatory, Gudali, Kistama, Darutippa, Ongole, Dánapa.*

In 1890-91 Lieut. Lenox Conyngham, R.E., observed for latitude between the Kistna and the Madras Coast, and thus completed Mr. Hennessey's programme on the meridian of  $80^{\circ}$ .

During this season the Zenith Telescope was first used in India, and Talcott's method of observation was introduced (see Plates I to III). Lieut. Lenox Conyngham was the pioneer who initiated the new method of observation, and his work has formed a lasting foundation for the Talcott system in India.

*Season 1892-93.*

*Latitude Stations visited.*—*Sonáda, Chaniána, Deesa, Oria (formerly called Gúru Sikkar), Samdari, Thob, Chamu, Jambo. Rájpur, Dehra Dún Base-line East End, Colába, Mándvi, Dhauleshvar, Khánpisura, Kanheri, Nitali, Achola.*

Captain Burrard commenced observations in Gujarát and worked northwards into the Rajputana desert. He employed Strange's Zenith Sector No. 1. This instrument had been used by Colonel Campbell in 1871-72, but its results had proved unsatisfactory, and it had been condemned. Campbell had found the curious fact that although the two zenith sectors were apparently alike, yet his, the No. 1, gave large differences between north and south stars, and measured all zenith distances in excess of the truth.\* In 1892 Burrard obtained permission to give it a further trial: he pointed out that if it had been used as a zenith telescope, the (N—S) difference would never have been discovered†, and that even the new zenith telescope might exhibit a similar difference, if it were employed as a zenith sector. At three stations Burrard used the instrument both as a zenith sector and as a zenith telescope, and observed for latitude both by the sector and Talcott methods. His mean results by the two methods agreed very closely, but the sector exhibited the same (N—S) difference, even to the last decimal place, as it had done in Campbell's hands 22 years before. The accordance of Burrard's results by the sector and Talcott methods removed the stigma from the instrument and the latter has been frequently employed since, and has won the confidence of successive observers. In Appendix No. 3 of this volume is given an account of the investigation of the (N—S) difference.

During this season Burrard introduced a modification of Talcott's method of observation, in that he occasionally observed a single star by Talcott's method instead of a pair: this could only be done with stars situated within half a degree of the zenith, of which four or five were generally available at every station.

In 1892 Lieut. Lenox Conyngham commenced the season by observing for latitude with the zenith telescope at two stations near Dehra Dún; he then moved to Bombay, and worked from west to east along the parallel of  $18^{\circ} 30'$ . Lenox Conyngham made an investigation into the effects of temperature upon the value of the micrometer screw, but he was unable to trace any connection between the observed changes in the value and the observed changes of temperature.

*Season 1893-94.*

*Latitude Stations visited.*—*Agra, Bithnok, Khirsar, Telu, Ládimsir, Mooltán, Dera Dín Panáh, Amritsar. Bolarum, Pirmulo, Vánákonda, Singáwáram, Parampúdi, Sánjib, Waltair.*

Capt. Burrard, working with Zenith Sector No. 1, started in the Rajputana desert, and continued his series of the previous year northwards into the Punjab.

\* See Volume XI, *Account of the Operations of the Great Trigonometrical Survey of India*, Chapter I, page (14).

† *General Report of the Operations of the Survey of India Department for 1892-93.*

Lieut. Lenox Conyngham, working with the Zenith Telescope, resumed his work of the previous season on the parallel of  $18^{\circ} 30'$  and extended his line of latitude stations eastwards to the east coast. Both observers experienced difficulties with their levels, and recommended the employment of two levels for observations by Talcott's method. The second level, which had always been used in Sector observations, was held to confer an advantage on the sector method over the Talcott.

*Season 1896-97.*

*Latitude Station visited.—Madras Observatory.*

The Madras Observatory was amongst the stations visited by Lenox Conyngham in 1890-91. It was an unfortunate coincidence that the first latitude observed in India with the new Zenith Telescope and by the Talcott method should have happened to be the latitude of an important astronomical observatory. Lenox Conyngham, moreover, had reported adversely upon his observations at Madras: he had, he wrote, constantly found his level unsteady, and he had been driven in consequence to design a wooden flooring for his tent. Being new to the instrument, he had been unable at Madras to locate the cause of the unsteadiness, and regarding his observations as experimental he had pushed on to his second station; the wooden flooring was then ready, and the unsteadiness of level disappeared.

In 1896 Mr. Michie Smith, the Director of the Madras Observatory, was about to complete a very important catalogue of stars, but was hindered by the uncertainty which surrounded the observed values of the latitude of the observatory. Lenox Conyngham, who was in England, strongly supported Mr. Michie Smith's proposal for a redetermination.

In the winter of 1896-97 Mr. Michie Smith and Major Burrard observed for latitude at Madras with both the Zenith Sector and Zenith Telescope. From a subsequent discussion of all results Mr. Michie Smith obtained a final value of  $13^{\circ} 4' 8''.0$ .\*

*Season 1897-98.*

*Latitude Stations visited.—Agra Longitude station, Agra parade point, Agra-group north point, Agra-group east point, Agra-group west point, Agra-group south point.*

In consequence of the simultaneous publication of the first volume of the Geodetic Survey of South Africa, and of a paper in the Philosophical Transactions of the Royal Society, entitled "India's Contributions to Geodesy", in which Sir David Gill and General Walker respectively recommended systems of "grouping" observed latitudes round a central station, it was considered advisable to introduce a series of "groups" into the Trigonometrical Survey of India; a similar system however had been initiated once before by Colonel Herschel, and had been abandoned after two years' trial.†

In 1897-98 Capt. Lenox Conyngham assisted by Lieut. Beazeley observed an experimental group of latitudes and azimuths round Agra; valuable experience of groups was gained, and the latitudes furnished interesting results: but the azimuths were not completed owing, firstly, to the delays caused by the observation of the Solar Eclipse, and, secondly, to the great expense of cutting trees, which would have been necessary, had the triangulation been perfected. One lesson learnt was that the vicinity of a great city was not a favourable locality for a "group".

On January 22nd, 1898, a total eclipse of the sun was visible in India, and many European and American astronomers visited this country. Capt. Lenox Conyngham was ordered to prepare a camp and observatories at Pulgaon in the Central Provinces for Mr. Newall and Capt. Hills, two of the observers selected by the Solar Eclipse Committee of the Royal and Royal Astronomical Societies. At the

\* *Madras Meridian Circle Observations*, Vol. IX. General Catalogue, 1899, pages xviii to xxi.

† Volume XI, *Account of the Operations of the Great Trigonometrical Survey of India*, page (13).

same time Major Burrard, who was in charge of the Tidal and Levelling operations, was directed to build observatories and prepare a camp at Sahdol in Rewah for Mr. W. H. M. Christie, F.R.S., the Astronomer Royal, and for Professor H. H. Turner, F.R.S.\*

In 1897-98 Lenox Conyngham increased the number of intersecting wires in the Zenith Telescope from one to three. The wires were separated by intervals of 1000 divisions of the micrometer; the object of the change was to obviate the necessity of traversing the single micrometer wire from end to end of the field when stars differing considerably in Zenith Distance were being observed. The exact distances between the several wires in terms of micrometer divisions were frequently measured.

#### Season 1898-99.

*Latitude Stations visited.*—*Daiádhari, Bhaorása, Sironj Base-line N.E. End, Kaliánpur, Súrantál, Kámkhera, Losalli, Tinsia, Ahmadpur.*  
*Vizagapatam Base-line N. End, Ráwal, Mal, Khundábolo, Cuttack, Patna Chandípur, Dariápur.*

In 1898-99 Capt. Lenox Conyngham observed a very complete and a very important group of latitudes and azimuths round Kaliánpur. His observations for latitude were taken with Zenith Sector No. 1, and those for azimuth with Barrow's 24-inch theodolite No. 2. His results were discussed by Major Burrard in Professional Paper No. 5 on "*the Attraction of the Himalaya Mountains upon the plumb-line in India*" published at Dehra Dún in 1901.†

In this paper deflections of the plumb-line were classified by regions, and were shown to follow one general law on all Himalayan meridians. It was also contended that the attraction of the Himalayan mass was being compensated not only by deficiencies of matter underlying the mountains, but by regular variations in the density of the Earth's crust under the plains of Northern India; and that the explanation of observed anomalies was to be sought in the abnormal densities of the crust underlying the plains, surrounding the mountains, rather than in a deficiency of matter below the Himalayan mass itself.‡ In this paper the futility of "grouping" latitude stations around a centre was demonstrated.

In 1898-99 Lieut. E. A. Tandy observed for latitude at stations on the East Coast of India: the instrument used was the Zenith Telescope, to which a second level had now been fitted. Tandy introduced this year a system of balancing pairs, by means of which the positive and negative corrections on account of micrometer value were equalised in the aggregate. This system was an immense improvement on the old.

#### Season 1899-1900.

*Latitude Stations visited.*—*Sarkára, Sirsa, Bánsagopál, Sankráo, Salámpur, Bostán, Chandaos. Amía, Karía, Háthbena, Ramai, Patháídi, Dalea.*

In 1899-1900 Lenox Conyngham observed for latitude with Zenith Sector No. 1 at stations in the Ganges Valley near the meridian of 78°. His object was to multiply stations in the vicinity of the Himalayas, and in those tracts where Himalayan attraction appeared to cease.

\* Report on "*the Total Solar Eclipse January, 22nd, 1898*" published under the direction of Major-General C. Strahan, R.E., Surveyor General of India, 1898.

† Also see Royal Astronomical Society, *Monthly Notices*, January 1902. *Report of the International Geodetic Conference*, Paris, 1900. Article on Mountain Masses and Latitude Determinations in "*Nature*", May 22nd 1902. Paper on the Figure of the Earth in the *Report of the British Association for the Advancement of Science*, Belfast, 1902, page 541. Papers on Deflections of the plumb-line in *Philosophical Magazine* for January and March 1904.

‡ The following extract is from an earlier paper by the same writer:—

"It is impossible of course to tell at *what* point on each meridian Himalayan attraction really ends, and when on the meridian of 78° we assume its limit is at Noh, where gravity first coincides with the normal, the absence of deflection may have been merely brought about by a counter-attraction from the south. It may be that Himalayan attraction extends much further south, and that about Lat. 26° it is merely neutralized by the Vináhyáchal and Sáppura ranges". *General Report of the Operations of the Survey of India Department*, for 1898-99, Latitude Operations, page xvi.

In 1899-1900 Tandy observed for latitude with the Zenith Telescope at six stations of the Biláspur Meridional Series. He also devoted much attention to questions concerning the accuracy of his levels; and took advantage of the two levels on his instrument to carry out a thorough investigation. He deduced a system of calibrating levels and invented an ingenious diagram, from which the true dislevelment for any position of the bubble, freed from errors due to deformations of tube, could be read off.\*

*Season 1900-01.*

*Latitude Stations visited.*—*Khankharia, Didáwa, Virária, Lúnki, Rojhra, Chánga, Khori, Alamkhán, Károthol, Akbar, Ranjítgarh.*

In 1900-01 Lieut. H. M. Cowie observed for latitude with the Zenith Telescope at eleven stations of the Great Longitudinal Series in the Rajputana and Sind deserts, and thus completed the chain of observed latitudes, which stretches across India from Calcutta to Karachi.

Lieut. Cowie introduced this year into the calculations of final mean values a system of weights, which has been followed in subsequent seasons.

He also introduced a system by which the level corrections were in practice reduced to a minimum. This was an outcome of Tandy's investigations: Tandy was the first to show the serious effect of the errors arising from levels; Cowie took a step further, and showed the possibility of escaping from these errors in practice. The probable errors of Cowie's results this season were not only smaller than had been attained with the Zenith Telescope before, but were the smallest on record.

*Season 1901-02.*

*Latitude Stations visited.*—*Madhupur, Charaldánga, Chanduria, Lohágara, Jalpaiguri, Siliguri, Kurseong, Senchal, Tonglu, Phallut.*

In order to test the correctness of the views put forward in the professional paper on Himalayan attraction and to discover whether southerly deflections would prevail over the east of the Gangetic plains as they had been shown to do over the west and centre, Cowie was deputed in 1901-02 to observe a series of latitudes on the meridian of  $88^{\circ}$  from Calcutta to Darjeeling. He found that the zone of southerly deflection was even more marked here than in other parts of the Ganges Valley, and that it extended northwards until the Himalayas were visible. At Kurseong he discovered a larger deflection of the plumb-line, than had yet been met with in India.

During this season Cowie made a thorough investigation of the value of the micrometer of the Zenith Telescope, and carried out a calibration of the screw.†

*Season 1902-03.*

*Latitude Stations visited.*—*Gúrmi, Majhár, Algi, Andhiári, Dargawa, Budhon, Saugor, Náhanmau, Birond.*

In October 1902 Lieut. Cowie was ordered to continue his tests of the previous season by working across the Gangetic plains over the supposed zone of southerly deflection along the meridian of  $79^{\circ}$ . He found as before that southerly deflections prevailed uninterruptedly throughout the zone. The instrument employed was the Zenith Telescope.

\* See Professional Paper—No. 4, "Notes on the Calibration of Levels," 1900.

† See Extracts from Narrative Reports of the Survey of India, for 1901-02—Latitude Operations.

During the summer of 1903 Cowie determined the systematic variations in the value of the micrometer of the Zenith Telescope by means of the "G" microscope of the apparatus used for comparisons of standards of length.

*Season 1903-04.*

*Latitude Stations visited.*—*Bahak, Bajamara, Lambatach, Kidarkanta, Kaulia, Mahadeo Pokra, Quetta.*

Perhaps the most extraordinary feature of Himalayan attraction is the sudden increase in the deflections of the plumb-line in the submontane region. On the meridian of Calcutta the extreme range of the deflections over 200 miles of alluvial plain was 3": but in the eleven minutes of latitude between Siliguri and Kurseong the deflections increased by 28". A similar peculiarity exists at Dehra Dún, and Birond. These sudden increases were as little to be predicted from the laws of gravitation, as was the prevalence of southerly deflections over the plains south of the mountains. They indicate that the real distribution of mass in the submontane regions is very different from what it appears. Consequently in 1903 it was decided to investigate the deflections of gravity in the inner Himalayas, and Lieut. Cowie was ordered to extend the triangulation of the Great Arc of India northwards across the Mussooree range to the snows, and to observe for latitude at all convenient points.\* His results were very remarkable, and showed that large deflections of 30" continued to prevail within the heart of the Himalayas.

The natural difficulties of the Himalayan problem have been increased by the exclusion of observers on political grounds from Nepal, for Nepal is most favorably situated for geodetic work. In 1903 Captain H. Wood was received at Katmandu by the Nepal Durbar, and was allowed at the special request of Lord Curzon to observe at two stations in the vicinity. The immediate object of Wood's visit was to identify the peaks of Mount Everest and Gaurisankar, and to settle points of geographical interest which had been under discussion for 50 years. Wood was however well aware of the value attaching to geodetic observations in Nepal, and seized the opportunity of observing an astronomical latitude at two stations near Katmandu, the geodetic positions of which he fixed by observations to well-determined snow-peaks. The only instrument that he had with him was a 6-inch micrometer theodolite—an instrument that is not generally considered suitable for rigorous astronomical work: but his results have been given a place in this volume beside those obtained with larger instruments, both on account of the skill displayed in difficult circumstances by the observer and in view of the small present probability of any further geodetic work becoming possible in Nepal.

After leaving Nepal Captain Wood was employed in observing astronomical azimuths at longitude stations: at Quetta he observed for azimuth and latitude with a 12-inch micrometer theodolite.

*Season 1904-05.*

*Latitude Stations visited.*—*Dehra Dún Haig Observatory, Nagarkhána†, Akyab, Prome, Moulmein.*

In 1904 Captain Cowie accompanied the Tibet Frontier Mission to Lha-sa. Upon his return he observed the latitude of Dehra Dún, and of four longitude stations in Lower Burma.

\* A chart of Cowie's Himalayan triangulation is given at the end of this volume. A description of his work will be found in Appendix No. 2.

† Nagarkhána is six miles from Chittagong Longitude Station.

## CHAPTER II.

### THE INSTRUMENTS EMPLOYED AND THE METHODS OF OBSERVING.

#### 1.

##### *The Zenith Sectors. Description of the Instruments.*

The construction of two zenith sectors, intended for the determination of Astronomical Latitudes, was sanctioned by the Secretary of State for India in 1861, and the task of designing them and superintending their manufacture was entrusted to Colonel A. Strange, F.R.S., who was at that time employed in preparing other instruments for the Great Trigonometrical Survey, and who was shortly afterwards appointed Inspector of Scientific Instruments to the India Office. The zenith sector is intended, as its name implies, for observing the meridional zenith distances of stars, not far distant from the zenith. Its distinguishing feature may be described as a construction which allows of its being turned on a vertical axis through  $180^\circ$  in azimuth between two observations of the same star about one culmination, a provision which admits of zero error being eliminated by treating the two observations as a pair to be combined together. It was not an instrument in common use, and but few had ever been constructed before Strange undertook the task. The chief points he had to keep in view were lightness and portability, so far as compatible with the desired power of the instrument, which was to be on a par with the highest class of field instruments, as distinguished from those of fixed observatories. Strange did not consider that any existing type of zenith sector—the best known being that by Sir G. Airy—would afford the desired portability; and he designed the new instruments on entirely novel lines. Their manufacture was entrusted to Messrs. Troughton and Simms, but was delayed in various ways, and the instruments were not completed for several years, No. 2 being sent out to India in 1869 and No. 1 in 1871. The experience gained in India in the use of No. 2 led to some modifications in No. 1. A detailed description of the zenith sectors is given in the second Chapter of Vol. XI of this series, and a drawing of one of them is appended to this volume as Plate IV.

#### 2.

##### *The Zenith Sectors. Method of observing.*

The programme of work with a zenith sector at a latitude station was drawn up in accordance with the following rules:—

- (i). From 70 to 100 stars were observed, 100 when possible.
- (ii). Each star was observed once E. to W. and once W. to E.\* In order that this might be done without confusion, a programme of stars was commenced on its first night with the first star E. to W., the second W. to E., and so on alternately: on the second night the first star was taken W. to E., the second E. to W., and so on.
- (iii). Four or six nights were devoted to each station: four were considered sufficient, if there was a paucity of stars and no misses occurred; but six allowed of stars that had been missed being observed in their second direction E. to W. or W. to E.
- (iv). When half the observations had been secured, the instrument was revolved through  $180^\circ$  in azimuth, *i.e.*, if the azimuthal stud had been originally placed north, it was brought round to south.
- (v). If only 70 stars were observed, they were divided into two programmes of 35 each: during the first night the first programme was worked through, during the second the second programme, and during the third those stars of both programmes that had been missed, were observed: on the morning of the fourth day the instrument was reversed, and in the evening the first programme again worked through, those stars taken E. to W. on the first and third days being now taken W. to E., and *vice versa*: on the fifth night the second programme was again taken up, the direction E. to W. and W. to E. being changed for each star from what it was on the second night: on the last night those stars of both programmes that had been missed during the fourth and fifth nights were observed.

\* "Observed W. to E." means that the first intersection of the star was made with the telescope west, and the second intersection with the telescope east.

- (vi). If 100 stars were taken, they were divided into three programmes: each programme was worked through once with the azimuthal stud north, and once with it south: those stars observed E. to W. on the first occasion of each were taken W. to E. on the second, and *vice versa*. As three programmes had to be got through in six nights, no spare nights were available for picking up misses, but by judicious interchanges of stars between the three a star missed from one programme could often be observed again in one of the other two.
- (vii). The number of observations per station were not to exceed 200, and were not to be less than 140.\*

The selection of stars for latitude observations was strictly regulated as follows:—

- (i). All stars were taken from the latest authorised catalogue.
- (ii). No star was considered sufficiently trustworthy for observation unless its north polar distance was shewn in that catalogue as determined by at least six observations.
- (iii). No star was included that had not a proper motion in north polar distance assigned to it in the catalogue.
- (iv). Double stars and stars of the 1st and 2nd magnitude were avoided.
- (v). No star was included that had a greater zenith distance than  $13^{\circ}$ .
- (vi). The number of north stars had to be the same as the number of south.
- (vii). The mean zenith distance of all the north stars was not permitted to differ from the mean zenith distance of all the south by more than half a degree.
- (viii). Stars that were  $8^{\circ}$  from the zenith or more were paired as nearly as possible.
- (ix). The minimum difference in right ascension between two consecutive stars was six minutes.
- (x). Two to four Nautical Almanac stars, equally distributed north and south of the zenith, were included to enable the chronometer error to be determined.
- (xi). Two to four stars within  $1^{\circ}$  of the zenith were included to enable the collimation error in azimuth to be determined.

The programme of work for one night was made up as follows:—

- (i). The zenith distances of about 36 zenith stars were measured, the stars being selected in accordance with the above rules, and each observed in both telescopic positions.
- (ii). The time of transit of a circumpolar star, whose right ascension had been well-determined, was taken over two wires in each telescopic position: from this was deduced the deviation error of the instrument.
- (iii). The transit-axis level was read before and after work in both telescopic positions.
- (iv). The two thermometers outside the tent were read every 15 or 20 minutes.
- (v). The barometer was read every hour, the mercury in the cistern being lowered and raised again to the zero pointer each time.
- (vi). The microscope run was determined 12 or 15 times, the same 5' space never being utilised twice; the high reading was always recorded *above* the low, whether read first or not.
- (vii). It was considered of importance that the temperature of the interior of the observatory tent should not differ from that of the outside air by more than  $1^{\circ}$  or  $2^{\circ}$  Fahrenheit: the thermometer attached to the barometer was therefore occasionally glanced at, but its readings were not recorded.
- (viii). The error of the chronometer and the collimation error of the telescope in azimuth were found nightly, but no special observations were needed for their determination, if in the selection of stars attention had been paid to rules (x) and (xi) given above.

### 3.

#### *The Zenith Sectors. Specimen of Record and Reduction.*

An extract from the original field records is given as a specimen of the form in which the zenith distance observations were entered and reduced. The first four columns call for no remarks: the next

\* It will be found, as a rule, that all the observations taken on any one particular night will be burdened with some small constant error, running throughout; the more nights therefore that the observations are extended over, the better will be the final result.

five contain the readings obtained from the sectors by means of the index microscope and the four microscopes A, B, C, and D. The fifth column is the mean of the preceding four. The column headed "c'" gives the correction for the average run of the microscopes. The average run was obtained at each station by repeated observations: at Chaniána the mean value of the run was determined from the following observed equation:—

$$299.429 \text{ divisions of mean microscope micrometer} = 300 \text{ seconds of arc,}$$

and the correction for run was

$$+ 0''.00190 \text{ per micrometric division.}$$

As a general rule the division of the limb *nearest* to a micrometer zero was intersected by the micrometer: if by any chance this rule was not adhered to, or if any doubt existed as to which division was nearest, a note was made on the record thus "Referred to 15' division."

In the twelfth column  $m$  is the reading of the eye-piece micrometer, but to obviate the necessity for + and - signs 5000 divisions are added—in other words the zero line is put back half an inch, for 100 revolutions go to the inch, and there are 100 divisions in the screw-head.

The next four columns contain the readings of the two levels, which are named "a" and "b" their ends being named  $n$  and  $s$  for reference.

The column  $M = \mu m$  is simply the reading  $m$  of the eye-piece micrometer reduced to seconds by multiplying by  $\mu = 0''.425456$ , the value in seconds of one division of the micrometer.

Refraction was taken from Bessel's Tables. The collimation and deviation errors and the dislevelment of the transit axis were measured frequently during work.

Stars observed with the zenith sector have to be intersected in *both* positions of the instrument, and the two intersections cannot consequently be made on the meridian: it has been usual to make the first intersection 20 seconds before the star reaches the meridian, and the second intersection 20 seconds after its transit. The interval of 20 seconds was estimated by means of the known intervals of the vertical wires from the centre wire. The *observed* zenith distance has therefore always received a correction on account of the extra-meridional position of the star at the time of intersection, due in the first place to the observations having of necessity been made off the centre wire, and in the second to the centre wire not having coincided with the meridian owing to imperfect adjustment of the instrument.

There were four causes which prevented stars being intersected *on* the meridian: they were (i) Intentional intersection off the centre. (ii) Collimation error. (iii) Inclination of the transit axis. (iv) Deviation error. The collimation and deviation errors and the inclination of the transit axis were always determined and entered on the record.

In the case of both intentional intersection off the centre and of collimation error the zenith distance of a star was measured on a small circle parallel to the meridian: in the case of dislevelment of the transit axis the measurement was made on a great circle cutting the meridian in the north-and-south diameter of the horizon: in the case of deviation error the measurement was made on a great circle cutting the meridian at the nadir and zenith.

Intentional intersection off the centre and collimation error have been treated together: the corrections to zenith distances depending on these two causes have been computed from the formula,  $\frac{15^2}{2} \cdot (k^2 + c^2) \tan \delta \sin 1''$ ,  $\delta$  being the star's declination,  $c$  the collimation error in time and  $k$  the estimated interval in time that the intersection was made from the centre wire. Zenith distances of north stars have been decreased and those of south stars increased by this expression.

If at the time of observation of a zenith distance ( $\zeta$ ) the transit axis was inclined to the horizon at an angle  $\theta''$ , the distance as observed has been, if the star were north, decreased by  $\frac{\theta^2}{2} \cdot \frac{\cos(\Delta + \zeta) \cos \zeta}{\sin \Delta} \sin 1''$ , and if the star were south, increased by  $\frac{\theta^2}{2} \cdot \frac{\cos(\Delta - \zeta) \cos \zeta}{\sin \Delta} \sin 1''$ ,  $\Delta$  being the North Polar Distance of the star.

If at the time of observation the deviation error of the instrument from the meridian was  $\alpha''$ , the observed zenith distances of north stars have been decreased by  $\frac{\alpha^2}{2} \cdot \frac{\sin(\Delta + \zeta) \sin \zeta}{\sin \Delta} \sin 1''$ , and those of south stars decreased by  $\frac{\alpha^2}{2} \cdot \frac{\sin(\Delta - \zeta) \sin \zeta}{\sin \Delta} \sin 1''$ .

## 4.

*The Zenith Telescope. Description of the Instrument.*

A zenith telescope was first used in India in 1890: it is a simple instrument and weighs but one-tenth of what a zenith sector does. So far the Survey of India has only purchased one zenith telescope proper and that was constructed by Troughton and Simms. The zenith sectors have however been used as zenith telescopes, and though they are unnecessarily heavy being encumbered with a vertical arc, they have proved suitable for observations after Talcott's method.

The distinctive feature of the Talcott method is that instead of the meridian zenith distance of a star being measured by means of a graduated limb, the difference between the meridian zenith distances of two stars on opposite sides of the zenith is measured by means of a micrometer. Thus if  $\lambda$  denotes the latitude of the station,  $\zeta_n$ ,  $\zeta_s$  the zenith distances of the stars, one north and the other south of the zenith, and  $\delta_n$ ,  $\delta_s$  their declinations, we have

$$\begin{aligned}\lambda - \zeta_s &= \delta_s \\ \lambda + \zeta_n &= \delta_n \\ \text{and therefore } \lambda &= \frac{\delta_s + \delta_n}{2} + \frac{\zeta_s - \zeta_n}{2}\end{aligned}$$

The zenith telescope is designed for the measurement of the quantity  $(\zeta_s - \zeta_n)$ .

Three plates illustrating the zenith telescope made by Troughton and Simms for the Survey of India are given in this volume. The telescope, the aperture of which is  $2\frac{1}{2}$  inches and focal length 30, is fixed at one end of a short horizontal axis, and is counterpoised at the other. The horizontal axis is fixed to a vertical axis, about 14 inches high; the latter is of steel and is supported by a tripod. The tripod rests on three levelling screws and is fitted with an azimuthal setting circle. The latter is provided with two stops which can be clamped  $180^\circ$  apart, so that the telescope can be brought into the meridian in both positions without reference to the limb of the circle. The telescope carries a setting circle and two sensitive levels.\* The reticule consists of the ordinary five transit wires and three transverse wires moved by a micrometer screw of long range, by which an angle of  $40'$  may be measured in zenith distance.†

When first used in India the zenith telescope was erected on a wooden stand, which was supported by a masonry foundation. The stand was however found to be affected by variations in humidity and temperature which rendered it unsteady and made frequent readjustments of the level necessary. This was troublesome and the stand has now been discarded in favour of an isolated brick pillar (see Plates II and III.)

## 5.

*The Zenith Telescope. Adjustments and Constants.*

The permanent adjustments are four in number, namely:—

- (i). Stellar focus.
- (ii). Horizontality of the horizontal wire.
- (iii). Collimation of the central vertical wire.
- (iv). The zero of the setting circle.

\* The second level was added in 1893.

† Originally there was but one transverse wire: the other two were added in 1897.

In this instrument special attention has to be paid to the focus; the observer has to make sure that the adjustment is satisfactory before he begins regular work, for any subsequent change alters the angular value of a revolution of the micrometer.

There are three horizontal wires, A, B, and C, A being that which lies towards the smaller numbers of the micrometer comb. These wires will seldom be truly parallel, so that all cannot be made horizontal. The central one B is adjusted and the inclination of the others to it determined.

The adjustment for collimation in azimuth has usually been made by Gauss's method with two small theodolites as collimators. The small remaining collimation error was determined nightly from star observations.

The values of the following instrumental constants were determined frequently :—

- (i). The equatorial intervals of the vertical wires.
- (ii). The divisions of the head of the eye-piece micrometer.
- (iii). The divisions of the scales attached to the levels.

The diaphragm carries five vertical wires known respectively as i, ii, iii, iv and v, and so numbered that in the position telescope east a zenith star transits the wires in the order i to v; whilst in the position telescope west, wire v is the first wire reached and wire i the last. In both telescopic positions wire iii is the centre wire, from which the intervals of all the others are measured. Wire i is that nearest to the comb.

*The micrometer screw.* The determination of the value of a division of the eye-piece micrometer is one of the most important and at the same time one of the most difficult operations connected with the zenith telescope. Various methods have been tried, and the following is the procedure now adopted by this survey.

The quality of the screw is first examined by observations of slow-moving stars near the pole. These may be made either with the micrometer in its normal position, the star being at elongation, or with the micrometer turned through a right angle so that a star at culmination is moving parallel to the screw. The latter plan is the more convenient and there is less danger of error owing to imperfect knowledge of the refraction; but in the zenith telescope no simple means of revolving the micrometer through a right angle are provided. The elongation method has the advantage that, if any movement of the telescope in altitude takes place during the observation, it is noticed and can be measured by the level, whereas if a movement in azimuth takes place, while a star is being observed at culmination, the observer is rarely aware of it and cannot measure it. The instrument, however, if erected on a suitable pillar, is not liable to movements in azimuth so that the advantage alluded to is more theoretical than real. The method of observing is similar to that for determining the wire intervals, except that in an examination of the screw the star is caused to transit the same wire again and again, the wire being advanced by a suitable number of turns of the micrometer after each transit.

Micrometer screws are liable to two principal defects, the one being a continuous increase in value from one end to the other; and the second an irregularity with a period of one revolution. To detect the first, it is best to select stars about  $10^\circ$  from the pole and to observe transits from one end of the field to the other giving the micrometer 2 or 3 revolutions at a time; for the second very close circumpolars are required and the wire should be moved forward by a few divisions only. For both kinds of observation it is convenient to have an electric chronograph for recording the transits.

It has been considered advisable to determine the mean value of one division under the conditions which obtain during the latitude observations. For this purpose measurements of the differences of declination of well known stars are made, either on extra nights devoted to this purpose at each station, or at any convenient times during work each night. It generally happens that during a night's work there are unavoidable intervals between pairs of stars, and it is frequently possible to find two stars lying near each other both in declination and right ascension which may be observed for micrometer value. The

observation is precisely similar to one for latitude except that a semi-revolution in azimuth is not given to the instrument. Stars selected for the purpose are about 15' to 30' apart in declination; if less, the deduced value of the micrometer becomes largely affected by an error of observation; if more, parts of the screw are brought into play outside those ordinarily in use.

A list of stars for Talcott observations will almost always include some "double pairs," *i.e.*, two stars of northern and one of southern aspect, or *vice versa*, on the same setting. It is quite legitimate to use the observations of the couple that have the same aspect for a deduction of the micrometer value.

It is also possible and permissible to deduce the final value of the micrometer from the results of the latitude observations themselves, and this was formerly done; but the method just described is preferred for the following reasons:—

(1) It is generally possible to observe the same couples of stars at several consecutive stations by which means a satisfactory watch is kept on any variation in the value of the micrometer.

(2) When two stars are observed, one after the other, without the telescope having been moved in the mean time, the level correction is generally so small as to be negligible.

(3) As the two stars are not only at the same altitude, but also close together in the heavens, there is little probability of there being any difference in the atmospheric conditions under which they are observed.

(4) If there is any systematic error in the declinations given in the catalogue it will affect the places of stars which lie close together equally so that the difference between the two will be free from its effect.

As a rule four to six couples have been observed each night.

## 6.

### *The Zenith Telescope. Method of Observing.*

The observer prepares a programme of stars in pairs: for any pair the interval of right ascension is not greater than 15 minutes nor less than 1 minute, and the difference of zenith distance does not exceed 40'. In former years the stars were chosen from Greenwich Catalogues only, but of late the International Catalogue of fundamental stars by Professor Newcomb has been largely used: the name of the catalogue is entered against each star on the record of observation.

An observation may be described as follows: the recorder calls out the mean zenith distance: the observer sets to this with the setting-circle vernier and clamps the level firmly, swings the telescope towards the north till the bubbles of the levels float, and clamps the telescope; then with the tangent screw of the telescope, he carefully brings the bubbles to the centres of their runs.

He now seats himself, and having been informed of the position of the star, places the wire in the proper part of the field. One minute before transit, the recorder gives warning and the observer prepares to make the intersection. As soon as the star enters the field, the observer approximately intersects and calls out to the recorder the name of the wire he is using, and the reading of the position of wire B on the comb, *e.g.*, "wire C four thousand eight hundred." To view wire B he will generally have to traverse the eye-piece. Bringing the eye-piece back so that the star may be in the centre of the field he completes his intersection, placing the wire exactly on the star as it crosses the central vertical wire, the last motion of the micrometer head being always in the screwing up direction; having done this he at once reads the micrometer head, estimating the nearest tenth of a division, and standing up reads both ends of the bubbles. This completes the observation of the first star.

He now releases the azimuth clamp and revolves the instrument through 180° bringing the clamp block up against the other stop without jerk or jar. After allowing sufficient time for the levels to come

to rest, the observer examines them, and if the readings have changed by more than about two divisions he brings the bubbles back to their original positions by means of the tangent screw, which moves the telescope as a whole.\*

The second star traverses the field on the opposite side of the centre of the comb, and at the same distance from it, so the observer has no difficulty in placing the wire in position. The observation is the same as in the case of the first star.

The level is read with as little delay as possible after the intersection has been made; if the bubble is observed to be moving when the reading is being taken the fact is recorded and the observation rejected.

The thermometers both inside and outside the observatory and the barometers are frequently read during work. The transit-axis level readings are recorded at the commencement and end of work for both positions of the telescope.

The programme always includes several stars from one or other of the almanacs; their times of transit are noted, so that the chronometer error and rate may be deduced.

Two or more circumpolar stars are observed for deviation error each night, one at least in each position of the telescope.

Lastly, one or more stars are observed for collimation error. For this purpose a star whose zenith distance is less than  $1^\circ$  is used. The observation consists in timing it over one of the vertical wires which it reaches before wire iii, and again timing it over the same vertical wire after reversal of the instrument.

At every station the wire intervals A to B and B to C are measured in terms of the micrometer. The intervals are required not only on the central vertical wire, but on each of the vertical wires so that if a star be intersected by A or C after passing wire iii the proper correction to reduce to B may be known.

These measurements can be best made in the day time. The telescope is pointed towards the northern sky, and the observer intersects with each of the moveable wires any convenient little speck or mark on each of the vertical wires in turn, recording in every case the reading of wire B. Several times during the season observations are made for determining the deviation of wire B from true horizontality.

The normal number of nights of observation at each station is six, and of programmes three, each programme being worked through twice over. These three programmes in the aggregate cover the dark hours, each consisting of 4 hours' work. Each programme contains about 20 pairs of stars.

It frequently happens that two stars of northern aspect occur in connection with one of southern, or *vice versa*, and these "double pairs" may be observed with advantage; a double pair does not yield so good a result as two independent pairs, but is better than a single pair. The method of weighting the result of such observations is explained hereafter; more than two stars on one side of the zenith should not be combined with one on the other side; but if a number of stars occur some north and some south, which can all be observed on one setting, it is a good plan to observe them without touching the level. The number of stars of each aspect are made as nearly equal as possible.

Two stars can be occasionally found which though both passing on one side of the zenith, are well placed for observation with the zenith telescope. Provided that their mean zenith distance is less than half a degree, Talcott's method can be applied to them in principle.

---

\* To use the tangent screw before observing the second star is slightly objectionable, as it may alter the strains in the telescope tube and produce flexure, or change such flexure as existed during the observation of the first star. There is less danger in doing this however than in allowing the level correction to be large.

One star only can be occasionally observed instead of the usual pair. As an example we may consider a star of zenith distance  $0^{\circ} 20'$ : the telescope is set to  $0^{\circ} 0'$  exactly; the star is intersected in one telescopic position; and the instrument is revolved  $180^{\circ}$  in azimuth and the star again intersected in the other telescopic position. The two intersections and the revolving of the telescope in azimuth are carried out during the transit of the star across the field of view; a star takes 40 seconds to transit the field, and 35 seconds is ample for the observation. The star in these cases is not intersected exactly on the meridian, and a small correction has to be applied to the zenith distance on this account.

A glance, at the fundamental formula will show that if the zenith distance of the south star of a pair is greater than that of the north the difference between them, as measured with the micrometer screw, is to be added to the mean of the declinations to find the latitude, and if less subtracted. In order therefore to cancel any error introduced by a faulty value of the micrometer the sum of the positive differences has to be made equal to the sum of the negative.

The use of double pairs, however, introduces a complication, for each result receives a fractional weight (the weight of an ordinary independent pair being unity). When the first rough draft of the programme is made, the extent and sign of the difference of zenith distance for each pair and its weight are entered; the algebraical sum of the weighted differences is then taken out, and if there is a considerable preponderance in either direction it is eliminated by the substitution of alternative stars. It is not as a rule difficult to bring about an approximate balance; though there may have to be some sacrifice of convenience, or even a reduction in the number of stars observed. It is useless to make the balance exact at this stage, for the accidental missing of a few stars, or the interference of clouds may disturb it; when the first part of the computations has been finished it is generally possible to secure a balance by the arbitrary rejection of one or two observations, if an approximate balance was designed at the outset. The difficulty of obtaining a thoroughly trustworthy value of the micrometer is so great, that it is important to arrange for the cancelment of errors arising from this source.

As there is a possibility of the existence of a personal error depending on the position of the telescope, it is desirable that every pair of stars be observed twice, once E. to W.\* and once W. to E.

## 7.

### *The Zenith Telescope. Record and Reduction.*

The computations may be divided into three principal parts:—

- (i) North polar distance of every star, and the mean of each pair.
- (ii) Difference of zenith distance of the stars of each pair.
- (iii) The final co-latitude.

(i) *North polar distances.* The authorities consulted for the places of the stars are the following:—Nautical Almanac, Berliner Astronomisches Jahrbuch, Connaissance des Temps, Greenwich catalogue for 1880, Newcomb's International Catalogue of fundamental stars.

For the computation of the apparent places Turner's edition of Stone's tables has been employed in recent years.

(ii) *Differences of zenith distance.* Let  $\zeta_n$  and  $\zeta_s$  be the true zenith distances of the north and south stars respectively, and let

$\zeta_0$  be the zenith distance to which the telescope is set,

$M_0$  the reading of the centre of the micrometer comb, viz., 5,000<sup>d</sup>,

---

\* Observed E. to W. means that the first star of a pair was observed with the Telescope East, and the second with the Telescope West.

- $M_n$  and  $M_s$  the micrometer readings of the stars,  
 $m$  the value of 1 div. of the micrometer,  
 $b$  the value of 1 div. of the level,  
 $R$  the reading of the right-hand end of the bubble,  
 $L$  the reading of the left-hand end of the bubble,  
 $l_n$  and  $l_s$  the level corrections  $= \frac{R - L}{2} b$ ,  
 $r_n$  and  $r_s$  the refraction corrections.

Two cases occur: in the first the micrometer reading increases with the zenith distance: in the second it decreases as the latter increases.

#### Case I.

The micrometer reading increases with the zenith distance if the south star is observed telescope east and the north star is observed telescope west.

$$\zeta_n = \zeta_o - (M_o - M_n) m + l_n + r_n$$

$$\zeta_s = \zeta_o - (M_o - M_s) m + l_s + r_s$$

The fundamental formula is

$$\text{co-latitude} = \phi = \frac{\Delta_n + \Delta_s}{2} + \frac{\zeta_n - \zeta_s}{2};$$

$$\therefore \phi = \frac{\Delta_n + \Delta_s}{2} + (M_n - M_s) \frac{m}{2} + \frac{1}{2} (l_n - l_s) + \frac{1}{2} (r_n - r_s).$$

#### Case II.

The micrometer reading decreases as the zenith distance increases if the south star is observed telescope west and the north star is observed telescope east.

$$\zeta_n = \zeta_o + (M_o - M_n) m - l_n + r_n$$

$$\zeta_s = \zeta_o + (M_o - M_s) m - l_s + r_s$$

$$\therefore \phi = \frac{\Delta_n + \Delta_s}{2} + (M_s - M_n) \frac{m}{2} + \frac{1}{2} (l_s - l_n) + \frac{1}{2} (r_n - r_s).$$

In case I the north star is observed in the position telescope west, and in case II the south star is observed in that position; hence in both cases

$$\phi = \frac{1}{2} (\Delta_n + \Delta_s) + (M_w - M_e) \frac{m}{2} + \frac{1}{2} (l_w - l_e) + \frac{1}{2} (r_n - r_s);$$

since the refraction increases with the zenith distance,  $(r_n - r_s)$  has the same sign as  $(\zeta_n - \zeta_s)$  and therefore the same as  $(M_w - M_c)$ .

Then as

$$\begin{aligned} \frac{1}{2} (l_w - l_c) &= \frac{1}{2} \left( \frac{R_w - L_w}{2} - \frac{R_c - L_c}{2} \right) b \\ &= \frac{b}{4} \left\{ (R - L)_w - (R - L)_c \right\}, \end{aligned}$$

so  $\frac{\zeta_n - \zeta_s}{2}$ , i.e., half the difference of zenith distance,

$$= D = (M_w - M_c) \frac{m}{2} + \frac{b}{4} \left\{ (R - L)_w - (R - L)_c \right\} + \frac{1}{2} (r_n - r_s).$$

In this formula it is assumed that there are no errors of adjustment and that each star is intersected as it crosses the central vertical wire. The corrections when these conditions are not fulfilled remain to be considered.

There are four sources of error:—

- (1) Intersection off the meridian.
- (2) Collimation.
- (3) Dislevelment of transit axis.
- (4) Deviation in azimuth.

The first and second are of the same nature. They cause the zenith distance to be measured on a small circle parallel to the meridian, instead of on the meridian itself.

Let  $k^s$  be the distance (in equatorial seconds of time) from the centre wire at which the star is intersected,  $c^s$  the collimation error:—

then the correction to an observed zenith distance is

$$\pm \frac{1}{2} 15^3 (k^s + c^s)^2 \cot \Delta \sin 1''.$$

The upper sign applies to south and the lower to north stars. It is clear from this formula that it would not be correct to treat  $k$  and  $c$  separately; if this were done a term  $= 15^2 kc \cot \Delta \sin 1''$  would be omitted, which might be appreciable.

An inclination of the transit axis causes the zenith distance to be measured on a great circle passing through the north and south points of the horizon and inclined to the meridian at an angle equal to the dislevelment.

Let  $b$  be the inclination to the horizon in seconds of arc; then whichever end of the axis is the higher, the correction to the zenith distance of a star is

$$\pm \frac{b^2}{2} \cdot \frac{\cos \phi \cos \zeta}{\sin \Delta} \sin 1''.$$

The upper sign is applicable to south stars and the lower to north.

A deviation in azimuth causes zenith distances to be measured on a great circle passing through the zenith and inclined to the meridian at an angle equal to the deviation.

Let  $\alpha$  be the deviation in seconds of arc; then the correction to a zenith distance is

$$- \frac{\alpha^2}{2} \cdot \frac{\sin \phi \sin \zeta}{\sin \Delta} \sin 1''.$$

The sign of the correction is independent of the star's aspect.

The following table shows the smallest values of  $(k + c)$ ,  $b$  and  $a$  which render corrections appreciable, *i.e.*, greater than  $0''.005$  :—

	Co-latitude $75^\circ$			Co-latitude $60^\circ$	
$\zeta = 0^\circ$	$\begin{cases} k + c = 8^s \\ b = 88'' \\ a = \text{Infinity} \end{cases}$		$\zeta = 0^\circ$	$\begin{cases} k + c = 6^s \\ b = 60'' \\ a = \text{Infinity} \end{cases}$	
$\zeta = 25^\circ$	$\begin{cases} k + c = 5^s \\ b = 82'' \\ a = 62'' \end{cases}$	$\begin{matrix} \text{Star N.} & \text{Star S.} \\ 10^s & 10^s \\ 93'' & 93'' \\ 71'' & 71'' \end{matrix}$	$\zeta = 25^\circ$	$\begin{cases} k + c = 4^s \\ b = 51'' \\ a = 57'' \end{cases}$	$\begin{matrix} \text{Star N.} & \text{Star S.} \\ 14^s & 14^s \\ 67'' & 67'' \\ 75'' & 75'' \end{matrix}$

This table shows that it is not difficult to keep the errors of adjustment small enough to render corrections inappreciable. It is not possible altogether to avoid intersections off the meridian, especially if the weather is cloudy, but they are resorted to as seldom as possible.

Various methods of computing the correction for refraction have been employed at different times but none have been found so satisfactory as that of computing the refraction for each star and taking the difference. The computation is effected by means of Bessel's Tables, published as a preface to the Greenwich seven-year catalogue for 1860.

(iii) *The final co-latitude.* When the co-latitude by each pair of stars has been computed, the combination of the individual values has still to be made. The method of combining the results has been different in different years. Sometimes arbitrary weights have been assigned and sometimes they have been derived from a discussion of the season's work.

Clearly all the mean results have not the same weight; those obtained from the components of double pairs have less weight than that from an independent pair; some pairs may only have been observed once, others twice or more often.

The proper increase in weight on account of a second observation depends upon the relative accuracy of the sum of two N. P. D's and of an observed difference of zenith distance. This could have been determined for each series of observations from an analysis of the results, but as such investigations\* are laborious, and as their effects on the final co-latitude are usually inappreciable the following method was adopted except where a series possessed exceptional features:

If  $\eta$ , the probable error of the mean of two declinations, be  $\pm 0''.20$ ; and  $e$ , the probable error of observation in a single determination of latitude, be  $\pm 0''.30$ , and if  $n$  be the number of observations,

$$\text{then weight} = w = \frac{1}{\eta^2 + \frac{e^2}{n}}.$$

\* Consult U. S. Coast and Geodetic Survey, 67th Annual Report, (1897-98) Appendix No. 7, p. 358. Chauvenet's Astronomy, Vol. II, p. 350. Doolittle's Astronomy, p. 508.

As the normal number of observations is two,  $w$  has been made unity for that value of  $n$ .

Whence if  $n = 1$ ,  $w = 0.7$ ,

2	1.0
3	1.2
4	1.3
5	1.4
6	1.5.

The case of a double pair has next to be examined.

Every value of the co-latitude may be considered to be made up of two parts, one for each star; we may therefore put  $c = p + q$ .

In the case of a double pair we have a second value

$$c' = p + q'$$

The mean of these two is

$$\frac{c + c'}{2} = p + \frac{q}{2} + \frac{q'}{2}$$

We may consider the probable errors of  $p$ ,  $q$  and  $q'$  to be each equal to  $e$ ,

$$\begin{aligned} \text{then } (p.e.)^2 \text{ of } \frac{c + c'}{2} &= e^2 + \left(\frac{e}{2}\right)^2 + \left(\frac{e}{2}\right)^2 \\ &= \frac{6}{4} e^2 \end{aligned}$$

Also  $(p.e.)^2$  of the result of a single pair  $= 2e^2$ .

Thus if  $w$  be the weight of the result of a single pair, and  $w'$  the weight of the mean result of a double pair

$$\frac{w'}{w} = \frac{2e^2}{\frac{6}{4}e^2} = \frac{4}{3}.$$

Therefore  $w'$ , the weight of the result of one component of the double pair  $= \frac{2}{3}w$ .

Hence if  $w = 1$ ,  $w' = 0.66$  or  $0.7$  nearly.

If a double pair be observed once only the result by each component has a weight of  $0.7$  on account of its belonging to a double pair, and of  $0.7$  on account of having been observed only once: on the whole therefore its weight is  $0.7 \times 0.7 = 0.5$ .

The balancing of the positive and negative micrometer differences is undertaken after the weights have been assigned. If the sums of the weighted differences are not equal they are rendered so by the rejection of a few observations. Those are selected for rejection in which the micrometer difference is large and the weight small.

Endeavours have been made to keep the difference between the sums so small that no error to which the micrometer value could reasonably be supposed liable, would have an appreciable effect on the mean co-latitude. Thus if in the value of one revolution there be an uncertainty of  $0''.05$  (an excessive estimate) and if  $d$  be the difference between the sums, expressed in revolutions, and  $\Sigma P$  the sum of the weights, then  $\frac{\frac{1}{2}d \times 0.05}{\Sigma P}$  should not exceed  $0''.005$ .

The final value of the co-latitude is equal to the sum of all the weighted means divided by  $\Sigma P$ .

If  $v$  be the difference between the final co-latitude and an individual mean value and  $n$  the number of individual values, the probable error corresponding to the unit of weight is  $\cdot 6745 \sqrt{\frac{\Sigma(Pvv)}{n-1}}$ .

and that of the final co-latitude  $\cdot 6745 \sqrt{\frac{\Sigma(\bar{P}vv)}{(n-1)\Sigma P}}$ .

## 8.

*Latitude Observations with Theodolites.*

*Station Kaulia.* Captain Wood observed for latitude on three nights. On each night 8 to 12 observations were taken of both a north and south star at transit. The chronometer error was obtained each night from observations of east and west stars near the prime vertical. The instrument used was a six-inch theodolite by Troughton and Simms: it was erected on a wooden stand, and its limbs were read by two micrometers, of which one division represented 10".

*Station Mahadeo Pokra.* The same instrument and methods were employed as at Kaulia. The observations were however limited to two nights.

*Quetta Telegraph Office Station.* Circum-meridian observations for latitude were taken on four nights. Eleven pairs of stars were observed. The chronometer rates were determined from the observed transits of high and low stars.

The corrections for refraction were computed from Bessel's Refraction Tables.

The reduction to the meridian was computed by the formula:—

$$\delta\zeta'' = -2 \sin^2 \frac{\delta P}{2} \cdot \frac{\cos \lambda \sin \Delta}{\sin \zeta} \operatorname{cosec} 1'' + 2 \sin^4 \frac{\delta P}{2} \left( \frac{\cos \lambda \sin \Delta}{\sin \zeta} \right)^2 \cdot \cot \zeta \operatorname{cosec} 1''$$

where  $\zeta$  is the zenith distance of the star,  $\Delta$  its north polar distance,  $\delta P$  the interval in time before or after transit and  $\lambda$  the latitude of the station. The second term is not required when the zenith distance exceeds  $40^\circ$  and the interval of time from transit is under 5 minutes.

## CHAPTER III.

### THE ANGULAR VALUE OF A REVOLUTION OF THE MICROMETER SCREW OF THE ZENITH TELESCOPE.

#### 1.

##### *Methods of Determination.*

The following methods have been employed to determine the angular value of a revolution of the micrometer screw :—

- (1). The observation of transits of circumpolar stars at elongation was the first plan adopted.
- (2). Then the several values for latitude given by the individual observations were discussed and utilized to provide a value.
- (3). Finally the measurement of the known difference of declination of stars of nearly the same right ascension was found to give the most satisfactory results.

The first method is discussed in Chauvenet's "*Spherical and Practical Astronomy*" and in Doolittle's "*Practical Astronomy as applied to Geodesy and Navigation*." It was tried in India in 1890-91 when the zenith telescope was first being employed, but the micrometer value obtained was not used in the reduction of the latitude observations.

When the second method is being employed the observations for latitude have to be reduced with the aid of a preliminary and assumed value for the micrometer. Each observed pair of stars then gives an equation of the form

$$\phi + \delta\phi = \frac{1}{2}(\Delta_1 + \Delta_2) + \frac{1}{2}(M_w - M_e)(\mu + \delta\mu) + \frac{1}{2}(l_w - l_e) + \frac{1}{2}(r_w - r_e)$$

where  $\mu$  is the preliminary micrometer value,

$\delta\mu$  the correction to  $\mu$ , which is to be deduced,

$\phi$  the co-latitude resulting from the use of the value  $\mu$ ,

$\delta\phi$  the correction to  $\phi$  following on the correction  $\delta\mu$ .

From a series of equations of this form  $\delta\mu$  and  $\delta\phi$  can be determined. This method was utilized prior to 1896.

When the third method is being adopted, the procedure is as follows :—

Two stars, differing in right ascension by from  $1^m$  to  $20^m$  and in declination by from  $15'$  to  $30'$ , are selected. The telescope is placed in the meridian and set to the mean zenith distance of the stars, and the bubble of the level brought to the centre of its run. As each star transits the meridian it is intersected with the micrometer thread. The difference of N.P.D's of the two stars corrected for refraction and for change of level during the observation is thus given in terms of the micrometer; and the value in seconds of arc of one revolution of the micrometer screw can now be deduced by means of the formula

$$M - m = \delta\Delta - \delta r - \frac{1}{2}\{(R - L) - (R' - L')\}$$

where

- $M - m$  is the difference of micrometer readings,  
 $\delta\Delta$  the difference of N. P. D's of the two stars,  
 $\delta r$  the difference of refraction for the two stars,  
 $R$  and  $L$  the level readings corresponding to the micrometer reading  $M$ ,  
 $R'$  and  $L'$  the level readings corresponding to the reading  $m$ .

This method was first employed by Captain Burrard in 1894 and has been utilized generally since 1896.

## 2.

### *Values of the Micrometer Screw.*

The following table gives the several values of a revolution of the micrometer of the zenith telescope, which have been adopted at various times in the reduction of the observations:

#### *Micrometer value used in the various seasons.*

Season	Value for one Revolution of the micrometer	Method of determination
1890 - 91	69.345	From a discussion of the latitude results.
92 - 93	69.345	Value of season 1890-91 adopted.
93 - 94	69.355	From a discussion of the latitude results.
97 - 98	69.3338	From the measurements of known differences of declination.
98 - 99	69.197*	" " " "
1899 - 1900	69.1260	" " " "
1900 - 01	69.1198	" " " "
01 - 02	69.1270	" " " "
02 - 03	69.2200	" " " "
03 - 04	69.205	" " " "
* 1904 - 05	69.2252	" " " "

The large change of value which occurred between the seasons 1897-98 and 1898-99 was due to a change in the object glass. At the conclusion of the former season, the object glass, which had shown signs of a fungus growth on part of its surface, was sent to Calcutta to be cleaned and polished, and in this operation the curvatures of the surfaces of the lenses underwent slight changes, which were accompanied by an alteration in the focal length.

The change of value between the seasons 1901-02 and 1902-03 was due to the fact that, at the commencement of the latter the zero of the micrometer was altered in order to bring into play a portion of the screw, in which the variations of pitch were believed to be of a uniform nature.

\* In 1898-99 Lieut. Tandy calibrated the micrometer screw and represented his results graphically: his corrections were thus taken from a diagram.

## 3.

*Determination of the wire intervals BA and BC.*

In the zenith telescope the travelling frame of the micrometer is fitted with three parallel wires separated by intervals of nearly 10 revolutions. These are designated A, B and C, the wire moving over the lower readings being A, and that over the higher being C. When a star is being observed, the wire lying nearest to it is used for the intersection. The reading taken from the micrometer, however, is that of the reference wire B, and to deduce the true micrometer reading at which the star has been intersected it is necessary to apply to the recorded position of B the value of the interval between B and the actual wire used in the intersection.

When the wire A has been used, the corrected micrometer reading becomes Reading of B *minus* value of interval AB.

When wire C has been used the corrected micrometer reading is Reading of B *plus* value of interval BC.

The values of the intervals AB and BC have been determined as follows:—

A speck of dust or a well defined irregularity on the central meridional wire, about the centre of the field, was selected. The speck was intersected by wires A, B and C in turn and a micrometer reading taken at each intersection. The differences between the respective readings were measures of the intervals AB and BC.

The several measures of these intervals, determined at different times and used in the reduction of the latitude observations are given in the following table:—

Season	Number of revolutions of the micrometer in	
	AB	BC
1890 - 91	The micrometer was not fitted with the auxiliary wires A and C until 1897.	
92 - 93		
93 - 94		
97 - 98	9·794	9·946
1899 - 1900	9·971	9·969
1900 - 01	9·9818	9·9603
01 - 02	...	9·9690
02 - 03	9·9599	9·9854
03 - 04	9·9668	9·9871
1904 - 05	9·9661	9·9845

The auxiliary wire A failed at the commencement of the field season 1901-02 and in consequence, two wires only were in use during that year. Both wires were renewed before the following season.

## CHAPTER IV.

### AN EXPLANATION OF THE TABLES GIVEN IN PARTS II AND III OF THIS VOLUME.

#### 1.

##### *Arrangement of Parts II and III.*

Part II of this volume deals with astronomical latitudes, Part III with deflections of the plumb-line. In Part II have been given all the details of the latitude observations taken between 1885 and 1905: in Part III the latitude results of Part II have been combined and classified with those obtained prior to 1885, and which have already been published in Volume XI. The lists of Part III are therefore complete to date. As the latitude stations of Volume XI were numbered from 1 to 111, the numbering of those in this volume was made to commence from 112.

#### 2.

##### *Contents of Part II.*

Part II consists of three main divisions:—

- (i). Alphabetical List of Latitude Stations.
- (ii). Descriptions of Latitude Stations.
- (iii). Abstracts and Summaries of Observations and Results.

Of these the third alone requires any explanation. In order to reduce the number of forms and tables the abstract and summary for each station have been printed together and not separately as was done in Vol. XI. In the present volume each abstract of observations is followed immediately by its summary.

In the abstract the co-latitude by each star, when the sector method was employed, and by each pair, when the Talcott method was employed, is given for each day of observation.

The column "Position of Telescope during observation" takes the same form whether the observations have been made with the zenith sectors or the zenith telescope: with both instruments each observation is composed of two parts, one with the telescope to the east of the vertical axis, the other with the telescope to the west: in the case of the zenith sector each star observed is intersected twice, once with the telescope east, and once with the telescope west: in the case of the zenith telescope one star of each Talcott pair is intersected with the telescope east, and the other with the telescope west. The column headed "Position of telescope during observation" is intended to show whether the intersection with telescope east preceded or followed the intersection with telescope west. If it preceded, the letters E, W will be found entered in the column: if it followed, the letters W, E will be recorded.

The tripod of a zenith sector or zenith telescope can be erected on its stand in two positions, either of which is suitable for observation. The two positions are  $180^\circ$  apart in azimuth. Some observers have always noted on their records the position of the tripod during observation, and consequently for

some stations the abstract form will be found to contain a column headed "Position of Azimuthal Stud." This stud, by which the azimuthal adjustment was effected, could be placed either due north or due south of the vertical axis: though its position has been recorded, it is believed to be without significance. No effect on results has ever been found to ensue from a change in this position.

The sector and Talcott methods of observation have already been explained in Chapter II, and the system of weighting has been described: the meanings of the several columns in the abstract form will be found to follow directly from the explanations and descriptions of the methods and systems.

In the summary, which follows each abstract, the geodetic value of latitude is compared with the astronomical.

### 3.

#### *Geodetic Values of Latitude.*

The astronomical values of latitude are derived directly from observations of the stars: the geodetic values are computed from the triangulation. Differences between astronomical and geodetic values are regarded as measures of the deflection of the plumb-line. The geodetic values are however known to be incorrect, and their errors affect directly the deduced deflections of the plumb-line. The magnitudes of these errors cannot at present be precisely determined: they are due to two causes, *viz.*, (1.) to the adoption of an erroneous value of latitude for Kaliánpur, the origin of the triangulation, (2.) to the adoption of an erroneous figure of the earth in the calculations of the triangulation.

The adoption of an erroneous value of latitude for the station of origin has the effect of producing a constant error in every geodetic latitude and in every deduced deflection of the plumb-line. The actual error of observation in the latitude of Kaliánpur may be small, the error due to local attraction there may be large.

The adoption of an erroneous figure of the earth has the effect of rendering all differences of latitude as calculated through the triangulation from Kaliánpur incorrect, the greater the difference the greater being its error.

The fundamental value of latitude originally adopted for Kaliánpur in the geodetic calculations extending over the whole of India was  $21^{\circ} 7' 11'' \cdot 26$ . This was Colonel Everest's value and was deduced by him with the aid of the star-catalogues then available.

Date of observation	No. of stars	No. of observations	As deduced by Everest	As deduced from Everest's observations by Cole in 1890 from modern star catalogues
1824-25	17	388	$24^{\circ} 7' 11'' \cdot 8370$	$24^{\circ} 7' 10'' \cdot 76$
1839-40	36	1811	$11'' \cdot 0928$	$10'' \cdot 92$
1840-41	52	1529	$11'' \cdot 3175$	$11'' \cdot 18$
Everest's weighted mean ...			$24^{\circ} 7' 11'' \cdot 26$	

In 1901 Major Burrard deduced a new value for the latitude of Kaliánpur as follows:\*

Date	Observer		Value
			° ' " ± "
1824-25	Geo. Everest	... ..	24 7 10·76 ± 0·13
1839-40	Andrew Waugh	... ..	10·92 ± 0·08
1840-41	Geo. Everest and T. Renny-Tailyour	... ..	11·18 ± 0·07
February 1865	W. M. Campbell	... ..	11·44 ± 0·07
November 1865	W. M. Campbell	... ..	10·90 ± 0·07
1898-99	G. Lenox Conyngham	... ..	10·59 ± 0·08
	Mean ...		24° 7' 10·97

This later value has been utilised in recent investigations and discussions, and deserves a greater weight than Everest's value. But it has been considered advisable to adhere in this volume to Everest's value. This volume is one of a series, and the preservation of uniformity throughout the series is a desideratum. These volumes are published more for purposes of reference and record than as contributions to contemporary discussion, and it would only lead to confusion if the results of each successive volume were based on newly derived fundamental values. So long as observations are being increased and improved, the final mean values will be ever liable to correction.

The variation of latitude is a recent discovery; but little is as yet known of it, and it is not possible at present to apply any correction for it to observed latitudes, or to reduce the latter to one epoch. When so much uncertainty continues to prevail, and when the attainment of finality is nowhere in sight, it is safer in continuous records of observations and computations to adopt one value and adhere to it, than to introduce constant changes. The value of latitude that has been adopted for Kaliánpur in the geodetic calculations of this volume is therefore

$$24^{\circ} 7' 11'' \cdot 26$$

Similar arguments apply to the figure to be adopted for the earth. It is known that the major axis of Everest's spheroid is too small, and that the ellipticity of Clarke's is too great, and it is possible now to obtain a figure that approximates more nearly to the truth than either. But the subject is not closed, great investigations are even now in progress, and it would lead to chaos if in every new volume of this series the adopted figure of the earth was changed. Everest's constants have therefore been retained in the geodetic calculations of this volume, viz:—

$$\text{Semi Major Axis} = a = 20,922,932 \text{ feet}$$

$$\text{Semi Minor Axis} = b = 20,853,375 \text{ „}$$

$$\text{Ellipticity} = c = \frac{1}{300 \cdot 80}$$

$$e^2 = 0 \cdot 0066378$$

$$1 - e^2 = 0 \cdot 9933622.$$

\* See Professional Paper—No. 5, "The Attraction of the Himalaya Mountains on the Plumb-line in India," 1901.

## 4.

### *Contents of Part III.*

In Part III the final results of Part II are classified with those of Vol. XI. The latitude stations of Vol. XI were numbered from 1 to 111, and those of this volume have been numbered from 112 to 239.

Part III consists of three divisions :

- (i). An alphabetical list of stations, in which the details and dates of observation are given.
  - (ii). An alphabetical list in which the astronomical values of latitude are compared with the geodetic.
  - (iii). The differences between the astronomical and geodetic values are re-arranged and grouped by regions.

## ASTRONOMICAL LATITUDES.

### DESCRIPTIONS OF STATIONS.

With a few exceptions the stations at which latitudes have been observed are Principal Stations of the Indian Triangulation and are fully described in other volumes of the *Account of the Operations of the Great Trigonometrical Survey of India*; in such cases the serial number and the series of the triangulation in which the station occurs are given with an abbreviated description. Whenever the latitude observer has indicated the character of the surrounding country his remarks are added followed by his initials.

*Latitude stations 1 to 111 will be found described in Vol. VI.*

112. Achola Hill Station (No. IV of the Bombay Longitudinal Series, volume XII of the *Account of the Operations of the Great Trigonometrical Survey of India*) is situated in the lands of the village of Achola, taluk Udgir, district Bidar, Nizam's territory. It is on a small knoll about  $\frac{1}{2}$  of a mile N.W. of Achola. The knoll is about 150 feet in height and is capped with laterite. Nearly due N. of the station is a *dargah* in front of which stands a *dipmâl*  $2\frac{1}{2}$  feet square, the centres of these are distant 14.5 and 21.2 feet respectively from the station.

The directions and distances of the circumjacent villages are:—Talegaon N.E., miles 2; Vallândi S.W. and W., miles  $1\frac{3}{4}$ ; Daunhiparga S.S.E., miles  $2\frac{1}{4}$ ; and Chaunhiparga N.N.W., miles 3. The station consists of a perforated pillar of masonry having two marks.

[The Astronomical Station is coincident with the Trigonometrical Station. It is situated on the top of an isolated hill some 200 feet high, capped with laterite. A few similar hills are to be seen here and there on the horizon, but they are unimportant and there seems no reason to anticipate any local attraction.—G. P. L. C.]

Geodetic Latitude of the Astronomical Station =  $18^{\circ} 14' 18''.12$

113. Agra-group east point was fixed by special triangulation and is situated in a field about half a mile to the N.N.W. of Mahuakhera and about  $5\frac{1}{4}$  miles E by S. of the Agra Telegraph Office. It consists of a brick pillar 3 feet in diameter, sunk flush with the ground and bearing a circle and dot.

The Astronomical Station is coincident with the Trigonometrical Station.

Geodetic Latitude of the Astronomical Station =  $27^{\circ} 9' 21''.00$

114. Agra-group north point was fixed by special triangulation and is marked by a circle and dot on a brick pillar 3 feet in diameter, built on a small sandy mound some 6 feet high. This mound is situated about 170 yards east of the road which runs in a northerly direction from the Judge's Court of Agra to Poia Ferry on the Jumna. It is about 70 yards from a garden known as Radha Bâgh, close to the gate of which is the 6th milestone from Agra.

The Astronomical Station is coincident with the Trigonometrical Station.

Geodetic Latitude of the Astronomical Station =  $27^{\circ} 14' 14''.10$

115. Agra-group south point was fixed by special triangulation and consists of a pillar 3 feet in diameter built flush with the surface of the ground. It is situated about 10 feet to the west of the path leading over the Delhi-Agra Canal by a small brick bridge to the village of Patti Pachgaon. The village is about  $5\frac{1}{4}$  miles south of the Agra Telegraph Office and about  $1\frac{1}{2}$  miles east of the Gwalior road.

The Astronomical Station is coincident with the Trigonometrical Station.

Geodetic Latitude of the Astronomical Station =  $27^{\circ} 5' 38''\cdot51$

116. Agra-group west point was fixed by special triangulation and is situated about 5 miles west of Agra Telegraph Office. It lies to the north of and about 150 yards distant from the Fatehpur Sikri road, on a small mound in the open fields, and consists of a brick pillar 3 feet in diameter, which projects some 9 inches above the ground and is marked with a circle and dot.

The Astronomical Station is coincident with the Trigonometrical Station.

Geodetic Latitude of the Astronomical Station =  $27^{\circ} 9' 45''\cdot86$

117. Agra Longitude Station (*vide* volume IX of the *Account of the Operations &c.*) is situated in the enclosure of the Telegraph Office, 233 feet due south of the Telegraph Office station.

[The Latitude Station is coincident with the Longitude Station.—S. G. B.]

Geodetic Latitude of the Latitude Station =  $27^{\circ} 9' 39''\cdot93$

118. Agra parade point was fixed by special triangulation and is situated on the S.E. end of a mound which is the site of the grand stand of the race-course on the garrison parade ground. It consists of a brick pillar 3 feet in diameter, sunk flush with the surface of the ground and marked with a circle and dot.

The Astronomical Station is coincident with the Trigonometrical Station.

Geodetic Latitude of the Astronomical Station =  $27^{\circ} 8' 57''\cdot47$

119. Ahmadpur Hill Station (No. II of the Great Arc Meridional Series—Section  $18^{\circ}$  to  $24^{\circ}$ , volume VI of the *Account of the Operations &c.*) is situated on an artificial mound of very ancient date. It is on an isolated hill near the village of Ahmadpur, district Bhilsa of the Gwalior territories. A Hindu temple stands on the same mound to the W.

The pillar is solid, 3.75 feet in diameter and built of stones and earth; it contains two marks, the upper 5.38 feet above the lower, which is on a stone at the ground level. A platform 17 feet square surrounds the central pillar from which it is isolated by an annulus 3 inches wide. The large town of Bhilsa lies about 10 miles S.E.

[The station is 1,715 feet above mean sea-level and situated on a conspicuous hill of almost solid rock, which rises to a height of over 200 feet out of the low plain to the south of the Kalānpur plateau. The ascent from the east is easy but on the other sides somewhat precipitous; there are many similar hills at intervals on every side but none so large. The nearest is a small one about 2 miles to the south-east. The plain between Kāmkhera and Ahmadpur is about 1,430 feet above mean sea-level. The Latitude pillar is situated in the prime vertical of the Trigonometrical Station, and 51 feet east of it.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $23^{\circ} 36' 20''\cdot88$

120. Akbar Platform Station (No. XIX of the Jogi-Tila Meridional Series, volume IV of the *Account of the Operations &c.*) is situated on a mound in the tahsil of Gugera, pargana Fattipur, district Montgomery, and about a distance of  $\frac{1}{4}$  mile to the north of the dāk bungalow and encamping ground.

The pillar is solid, and raised about 3 feet above the surface of mound.

[The Latitude pillar is 210 feet W. of and 0.9 foot N. of the Trigonometrical Station which is on a mound some 80 feet high above the ground level. It is about  $\frac{1}{4}$  mile S.S.W. of the village of Akbar and  $\frac{1}{4}$  mile E.N.E. from the old fort of the same name. Akbar village is about 13 miles N. of Gambar Station N.W.R. There is no apparent local cause for deflection of the plumb-line.—N. M. C.]

Geodetic Latitude of the Trigonometrical Station =  $30^{\circ} 53' 43''\cdot26$   
Reduction to Astronomical Station = + 0.01

Geodetic Latitude of the Astronomical Station =  $30 53 43 \cdot27$

121. Akyab Longitude Station (*vide* volume X of the *Account of the Operations &c.*) is on the

meridian of the Telegraph Office station, 50·1 feet north of it, and about 20 feet west of the centre of the main building.

[The Latitude pillar is 24 feet 2 inches west of the Longitude Station, and 7 inches south of same. The Instrument stood upon a masonry pillar of the usual pattern. The Longitude Station and the Telegraph Office station (*vide* volume X of the *Account of the Operations &c.*) are in good condition. The marble slab and pillar referred to in Vol. X. p. (8) were not found in 1905. —H M C.]

Geodetic Latitude of the Longitude Station	=	20° 8' 12"·87
Reduction to Latitude Station	=	— 0·01
Geodetic Latitude of the Latitude Station	=	20 8 12·86

122. Alamkhán Tower Station (No. XCV of the Karachi Longitudinal Series, volume III of the *Account of the Operations &c.*) is situated in the Hyderabad collectorate of Sind. Alamkhán Sigari village is distant about 0·15 mile.

The pillar is 32 feet high, and carries eight mark-stones as follows:—One at level of foundation, the others 2, 8, 11, 20, 26, 31 and 32 feet respectively above it.

[The Latitude pillar is 40 feet E. of the Trigonometrical Station. There is no apparent cause for any deflection of the plumb-line. The Trigonometrical Station is in good order —H M C.]

Geodetic Latitude of the Astronomical Station	=	24° 49' 31"·23
---	---	----------------

123. Algi Hill Station (No. VIII of the Budhon Meridional Series, volume VII of the *Account of the Operations &c.*) is situated on a hill about 3 miles north of the hill fort and large village of Dinara: in the Gwalior State. The station is marked on the rock *in situ* around which a platform has been built.

The distances and directions of surrounding villages are:—Khirk 1·2 miles, N.N.W; Algi 1·1 miles, S.W; and Guraira Rāj Oreha 0·5 mile, due S.

[The Latitude pillar is 802 feet east of the Trigonometrical Station and the azimuth of the former from the latter measured from north by east is 90° E 3". The Trigonometrical Station is on a narrow ridge running approximately N and S, the Latitude pillar being on the flat at the foot of the slope. Considering its amount and distribution, the mass of the ridge can produce no appreciable deflection of the plumb-line in the meridian —H M C.]

Geodetic Latitude of the Trigonometrical Station	=	25° 29' 46"·20
Reduction to Astronomical Station	=	— 0·01
Geodetic Latitude of the Astronomical Station	=	25 29 46·19

124. Amritsar Longitude Station (*vide* volume XV of the *Account of the Operations &c.*) is situated in the compound of the Government Telegraph Office, and about 20 feet to the west of the main building.

[The Latitude Station is coincident with the Longitude Station. Himalayas visible to N.E. Marked northerly attraction to be expected here —S G B.]

Geodetic Latitude of the Latitude Station	=	31° 37' 58"·72
---	---	----------------

125. Amúa Hill Station (No. XVII of the Calcutta Longitudinal Series, volume VI of the *Account of the Operations &c.*) is situated in the Maihar district, and stands on the southernmost extremity of the Kaimúr range. The encamping ground of Siwaganj, on the high road from Mirzapur to Jubbulpore, is distant about 3 miles to the N. The station is marked by the centre of a circle engraved on a stone which is fixed on the surface of the platform, and placed perpendicularly over a similar stone at the base.

[The station is about 4 miles east of Jukehi station on the E. I. Railway. It is on the southern edge of a long range which stretches on indefinitely in a N. E. direction, at a uniform height of nearly 1,000 feet above the surrounding plain, the only other feature likely to effect local attraction perceptibly is another similar range N. W. of, and similar and parallel to the one on which the station is. The combined effect of these two might account for a deviation of the plumb-line of 4" N. E.—E.A.T.]

The Astronomical Station is coincident with the Trigonometrical Station.

Geodetic Latitude of the Astronomical Station	=	23° 59' 56"·24
---	---	----------------

126. Andhiári Hill Station (No. IV of the Budhon Meridional Series, volume VII of the *Account of the Operations &c.*) is situated on the highest point of the sandstone range of that name, and about 100 yards north of a remarkable cave: in the Gwalior state. The distances and directions of

the surrounding villages are :—Sirsod 0·4 mile, N. by W. ; Jamursa 2·1 miles, S.E. ; and Larheri 2 miles, S.W. The station consists of a solid pillar with a mark-stone at its upper surface.

[The Latitude pillar is 1080 feet east of the Trigonometrical Station, the azimuth of the former from the latter measured from north by east is  $89^{\circ} 57' 40''$ .

The Trigonometrical Station is on a narrow ridge and the only possible situation in the prime vertical for the latitude pillar was on the flat ground at the foot of the slope. The ridge however runs approximately north and south and is not capable of influencing the plumb-line by any appreciable amount in the meridian, though it may be expected to produce a deflection of not more than 1" west in the prime vertical.—H.M.C.]

Geodetic Latitude of the Trigonometrical Station	=	$24^{\circ} 41' 6'' \cdot 77$
Reduction to Astronomical Station	=	$+ 0 \cdot 01$
Geodetic Latitude of the Astronomical Station	=	$24 \ 41 \ 6 \cdot 78$

127. Ankora (or Rebálemba) Hill Station (No. XXXV of the Jabalpur Meridional Series, volume VI of the *Account of the Operations &c.*) is situated on the highest part of a very conspicuous hill ; pargana Sirpur, tahsil Chēnnūr in the territory of the Nizam of Hyderabad.

The station consists of a solid pillar having a mark-stone at its upper surface. The small village of Ankora lies at the foot of the hill 2 miles W., and the town of Sirpur about 5 miles N.

[The Latitude pillar is built on the Trigonometrical Station which is situated on the top of a hill 1500 feet high, the south and west sides of which are very precipitous but which slopes more gradually on the north-east side. The hill and the surrounding country are covered with a moderately thick tree jungle. Due north lies the valley of the Wardha river, a level stretch and due south there are no hills for 15 or 20 miles. On the east at a considerable distance there is a fairly high range of hills running N. and S. and from it a low spur runs out, terminating in two hills similar to Ankora and distant from it S.S.E. about 1 and 2 miles respectively. They are nearly as high as Ankora but not very massive. There is also a low range of hills about 5 miles off running from a little S. of W. up to N.W. Whatever local attraction there is will probably be south.—J. E.]

The Astronomical Station is coincident with the Trigonometrical Station.

Geodetic Latitude of the Astronomical Station	=	$19^{\circ} 24' 34'' \cdot 75$
---	---	--------------------------------

128. Bahak Hill Station was fixed by special triangulation and is on the highest point of the hill of the same name in the lands of the village Kaprole, Patti Mungar Santi (Tehri-Garhwāl) on the watershed of the Bhágirathi and Junna rivers, about  $2\frac{1}{2}$  miles E.N.E. of Tehliank village on the Burni stream, a tributary of the latter, and  $5\frac{1}{2}$  miles N.W. of Gula village on a stream which flows into the former between Gula and Thara villages.

The point is marked by the usual circle and dot inscribed on a stone. Over this lower mark is built a circular masonry pillar 2 feet 5 inches high and 3 feet in diameter carrying at the centre of its upper surface an upper mark vertically above the lower. Surrounding this pillar, but isolated from it, is a masonry platform 14 feet square and built to a level 3 inches higher than the top of the pillar.

The station is easily approached from the south from Chajoola village or from the west from Kaprole. There is a site for a small camp a short distance west of and below the station, but the nearest good water is over 2 miles in the same direction.

[The Latitude pillar is 5 feet 11 inches south and 24 feet  $3\frac{1}{2}$  inches east of the Trigonometrical Station.—H.M.C.]

Geodetic Latitude of the Trigonometrical Station	=	$30^{\circ} 45' 5'' \cdot 28$
Reduction to Astronomical Station	=	$- 0 \cdot 06$
Geodetic Latitude of the Astronomical Station	=	$30 \ 45 \ 5 \cdot 22$

129. Bajamara Hill Station was fixed by special triangulation and is on the top of the peak locally known as Bajamara, on the watershed between the Tons and Junna valleys. The station is not identical with Bájámárá h.s. of Synoptical Vol. VII, which is 170 feet lower and about a mile to the west. A cairn of stones and a pole, possibly a triangulation signal, was found on the upper, but no such mark was found on the lower peak.

It is marked in the usual way by a circle and dot on a large stone found about 1 foot below the surface of the ground. Over this is built a circular masonry pillar  $1\frac{1}{2}$  feet high and 3 feet in diameter, carrying at its centre, on the upper surface, a second similar mark vertically over the lower. It lies in the lands of the village Khatt Kailana, District Dehra Dún, and is about 100 yards from the Chakráta-Mandali road which runs round the southern and eastern faces of the hill. The station is 2 miles from

Deoban Forest Bungalow and  $3\frac{1}{2}$  miles from Mandali Forest Bungalow. There is no good camping ground near the station and good water is to be found only at a considerable distance.

[The Latitude pillar is 12 feet  $6\frac{1}{2}$  inches north and 46 feet 10 inches west of the Trigonometrical Station.—H.M.C.]

Geodetic Latitude of the Trigonometrical Station	=	30° 45' 56"·07
Reduction to Astronomical Station	=	+ 0·13
Geodetic Latitude of the Astronomical Station	=	30 45 56·20

130. Bánsopál Tower Station (No. XXXV of the Budhon Meridional Series, volume VII of the *Account of the Operations &c.*) is situated on a sandy mound (7 or 8 feet in height) distant 500 yards west of the temple of Bánsopál, a place of Hindu pilgrimage: tahsil and pargana Sambhal, district Moradabad.

The station consists of a tower of unburnt bricks and mud cement, 14 feet in diameter at top, enclosing a central solid pillar of masonry 18·8 feet high: it has a mark-stone at a little below ground level, and another at summit. The distances and directions of surrounding places are:—Sambhal town 3 miles, N.E.; Turrano Sarai 1·8 miles, E. by S.; Gandhipura village 1 mile, N. by E.; Busla village 1·7 miles, W. by S.; and Bahádurpur Sarai 1·1 miles, S.W. by S.

[The Astronomical Station was situated 2429·7 feet west of the Trigonometrical Station. The azimuth of the latter from the former was  $270^{\circ} 1' 20''$  so that the Latitude pillar was 0·94 of a foot north of the prime vertical of the Trigonometrical Station.—G.P.L.C.]

Geodetic Latitude of the Trigonometrical Station	=	28° 33' 28"·07
Reduction to Astronomical Station	=	+ 0·01
Geodetic Latitude of the Astronomical Station	=	28 33 28·08

131. Bhaorása Hill Station [No. (V) of the Great Arc Meridional Series, Section  $24^{\circ}$  to  $30^{\circ}$ , volume IV of the *Account of the Operations &c.*] is situated on the highest point of a small rolling hillock of sandstone, which rises very gently from the general level of the plain to the south and west but falls more abruptly to the north and east. The Betwa river runs by the eastern end of the hill at a distance of about  $1\frac{1}{2}$  miles from the station. The height of the station above mean sea-level is 1,387 feet, but under 100 feet above the general level of the plain. The station lies in pargana Bhaorása of the Gwalior territories. The circumjacent villages, with their distances and directions are:—Bherkheri about 2 miles, N.W.; Kiria about 2 miles, N.E.; Salitra about 2 miles, S.S.W.; and Sarkandi about 2 miles, W.

The station consists of a solid masonry pillar, about 11 feet high and  $3\frac{1}{2}$  feet in diameter. It has a mark-stone at top, another at bottom, and a third between them.

[The Astronomical Station is situated 46 feet 3 inches from the Trigonometrical Station on an azimuth of  $269^{\circ} 17'$ . Before leaving the station a protecting pillar of the form of a square truncated pyramid, 3 feet 6 inches in height, was built over the Trigonometrical Station and a cairn of stones was heaped over all. The Latitude pillar was not protected.—G.P.L.C.]

Geodetic Latitude of the Trigonometrical Station	=	24° 8' 3"·73
Reduction to Astronomical Station	=	+ 0·01
Geodetic Latitude of the Astronomical Station	=	24 8 3·74

132. Bhímsain Hill Station (No. XXVI of the Jabalpur Meridional Series, volume VI of the *Account of the Operations &c.*) is on the boundary line between the tahsils of Bhandára and Sákoli in the Bhandára district of the Central Provinces. The villages of Manglee and Bandarjiri are 3 miles to the east. It lies in the lands of the village of Kotúrli.

The pillar is solid and contains two marks, the distance between which has not been measured; the height of the pillar is 6·67 feet.

[The Astronomical Station, which was built over the mark-stone of the Trigonometrical Station, is situated on the highest part of a conspicuous range of hills and slightly south of the centre of gravity of the mass. The direction of the range is east and west, but the northern slopes are more gradual than the southern; 2 miles N.E. is a small range 400 feet high, and 3 miles long: 7 miles to the N.W. is a rather larger range but of no great importance. The northern horizon is broken by hills here and there but their small height and great distance render them barely visible. The only mountains to be seen towards the south are a small cluster some 12 miles off lying in a south-westerly direction. All the hills mentioned above are of but small significance and their effects should be very slight. A more likely source of local attraction than any neighbouring mountains is the uniform slope of the ground downwards from

north to south, though this also should exercise no great effect on the astronomical latitude: the level of the ground at Eetan, 12 miles south of Bhímsain, is from 75 to 100 feet lower than that at Bhandára, 12 miles to the north, and the descent throughout is gradual. Taking the above facts into consideration, one may say that Bhímsain was a station well-suited for astronomical observations (as far as any station in the Central Provinces can be well-suited); a small local attraction say of 1", is expected here to the north.—S.G.B.]

The Astronomical Station is coincident with the Trigonometrical Station.

Geodetic Latitude of the Astronomical Station =  $20^{\circ} 57' 35'' \cdot 96$

133. Birond Hill Station (No. VIII of the North-East Longitudinal Series, volume VII of the *Account of the Operations &c.*) is situated in pargana Díánirao, thána Haldwáni of the Kumaun district and stands on the southern range of the Sub-Himalaya mountains. The village of Birond is distant about  $2\frac{1}{2}$  miles to the N.N.E.

The pillar is solid. It has a mark-stone at top, and a mark engraved on the rock *in situ*.

[The Astronomical Station coincides with the Trigonometrical Station. Immediately to north and south of the station, the ground falls rapidly to deep valleys, the bottoms of which are probably about 3000 feet above mean sea-level. The ridge including Birond peak runs, generally speaking, east and west. The station appears to be somewhat south of the centre of mass of the hill and a slight local disturbance to the north may be expected.—N.M.C.]

The Astronomical Station is coincident with the Trigonometrical Station.

Geodetic Latitude of the Astronomical Station =  $29^{\circ} 15' 14'' \cdot 15$

134. Bithnok Hill Station (No. XXXVIII of the Jodhpore Meridional Series, volume IVA of the *Account of the Operations &c.*) is situated on the highest sand-hill of a range running N. and S., locally called Gajath Thal, a few hundred yards south of a cart-track from Bithnok to Bagu village. The station is in the lands of that village in pargana Magra of the Bickaneer territories. The pillar is solid, surrounded by a platform of sand and stones. No mention is made of a mark-stone having been placed at the surface of the pillar. The azimuths and distances of the circumjacent villages are:—Bangarsar (approximately)  $141^{\circ}$ , miles 9 nearly; Bithnok  $275^{\circ}$ , miles 5.22; and Mandal  $323^{\circ}$ , miles 10 nearly.

[The Astronomical Station is coincident with the Trigonometrical Station. Perfectly flat sandy desert: plumb-line unaffected by hills.—S.G.B.]

Geodetic Latitude of the Astronomical Station =  $27^{\circ} 53' 22'' \cdot 03$

135. Bolarum Longitude Station (*vide* volume XV Appendix p. (8) of the *Account of the Operations &c.*) is 16.394 feet west, and 24.17 feet south of the old Longitude Station, which is in the compound of the Public Works Office, and 221.63 feet north of Bolarum P. W. D. Office station. Bolarum is the cantonment for a portion of the garrison of Hyderabad, the capital of the Nizam.

[The Latitude Station is identical with the new Longitude Station. To the north of Bolarum the general level of the country is higher than to the south, so that there may perhaps be some deviation of the plumb-line in the former direction, there is nothing in the immediate surroundings of the station to lead one expect any deviation.—G.P.L.C.]

Geodetic Latitude of the Latitude Station =  $17^{\circ} 30' 13'' \cdot 41$

136. Bolíkonda Hill Station (No. XI of the Bider Longitudinal Series, volume VI of the *Account of the Operations &c.*) is in táluk Warangal, Sar-táluk Khamamet of the Nizam's territories. The hill is sacred to Rámáswámi, a Hindu deity whose image is carved in relief in stone and placed with its stone attendants in a rude enclosure. The top of the hill is fortified and would afford a safe refuge to small bands of robbers: rain water in sufficient quantity to form a plentiful supply accumulates in a natural cistern in the rock within the walls. An annual fair is held on the hill top in honour of the god.

The station consists of a solid pillar of masonry having two marks, one in its upper surface and the other 6.00 feet below it. The azimuths and distances of the circumjacent villages are:—Inkúrti  $353^{\circ} 56'$ , miles 2.70; Bolíkonda (deserted)  $278^{\circ} 13'$ , miles 1.21; Tumapoili  $235^{\circ} 36'$ , miles 2.10.

[The Latitude pillar is built on the Trigonometrical Station situated on the top of a very steep rocky hill some 1,500 feet high. To the north there is an inextensive isolated hill 1,200 or 1,400 feet high and distant a mile and there is a similar hill at the same distance to the south. There is a smaller hill distant 2 miles to the north and two small ones about 2 miles N.W., but as the station is not quite over the centre of gravity of the hill on which it stands, the local attraction should be insignificant.—J.E.]

The Astronomical Station is coincident with the Trigonometrical Station.

Geodetic Latitude of the Astronomical Station =  $17^{\circ} 42' 35'' \cdot 82$

137. Bostán Tower Station (No. XXXVIII of the Great Arc Meridional Series, Section 24° to 30°, volume IV of the *Account of the Operations &c.*) is built on the high bank which bounds the bed of the river Jumna to the east in pargana Dádri of the Bulandshahr district. The adjacent villages are—Garabpur 3·9 miles, N.W., and Dádri 3·5 miles, N.E.

The station consists of a perforated pillar of masonry 50 feet high, having a mark-stone on the ground floor.

[The Latitude pillar was situated 722 feet east of the Trigonometrical Station. The azimuth of the latter from the former was 90° 0' 35", so that the latitudes of the two may be considered identical.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station = 28° 30' 59"·64

138. Budhon Hill Station (No. III of the Calcutta Longitudinal Series, volume VI of the *Account of the Operations &c.*) is situated immediately above the village of that name, thána Barodia, tahsil Kurai, pargana Banda, district Saugor. The station consists of a solid masonry pillar having three mark-stones, the two upper respectively 9 and 4 feet above the lowest. The distances and directions of surrounding villages are:—Jáman Kheri 1·5 miles, N.W.; Burruho 1·5 miles, N.; Dubri 1·3 miles, E.N.E.; Khirea 1·1 miles, E.S.E.; and Kanera 2 miles, due S.

[The Latitude pillar is 51 feet east of the Trigonometrical Station on the flat-topped hill immediately north of Budhon village near the northern edge of the top. Both to north and south the country is covered with jungle and anomalies of refraction are not to be expected. The immediate locality shows a deficiency of matter to the north and west to which one might attribute deflections of less than 0"·5 in amount to the south and east.—H.M.C.]

Geodetic Latitude of the Astronomical Station = 24° 5' 8"·41

139. Burgpaili (or Rájula Ghúta) Hill Station (No. XLI of the Jabalpur Meridional Series, volume VI of the *Account of the Operations &c.*) is situated about 2·5 miles E. of the village of Burgpaili; pargana and tahsil Chēnnúr of the Hyderabad States.

The station consists of a solid, masonry pillar 4·5 feet high having two marks, the distance between which is not known.

[The Latitude pillar is built on the Trigonometrical Station situated on a low narrow hill about 600 feet high. To the north there is nothing but the smallest of hills between the station and Ankora. In the immediate vicinity 1 mile to the S.W. there is a small hill about the same size as that on which the station is situated. Due south, distant 8 or 10 miles, there is a fair-sized conical hill and in the distance, 20 or 30 miles off, the very considerable range in which Ramgir is situated. The attraction should be small and to the south.—J.E.]

The Astronomical Station is coincident with the Trigonometrical Station.

Geodetic Latitude of the Astronomical Station = 18° 54' 7"·20

140. Chamu Hill Station (No. XVII of the Jodhpore Meridional Series, volume IVA of the *Account of the Operations &c.*) lies within the boundary of Chamu in taluk Ketu of the Jodhpur territories about a mile in a direction 42° E. of N. from it.

The pillar, which is solid and 3 feet high, has been sunk so that its surface is level with the ground and has been built on a circular foundation 6 feet in diameter and 1 foot in thickness, resting on wooden piles. It contains two marks one at the surface and the other at the bottom of the pillar. Barnán village lies about 4 miles N.W.

[The Astronomical Station is coincident with the Trigonometrical Station of Chamu. It is situated on a small sand-hill in the midst of an immense plain: with the exception of a few sand-hills and small rocky hills here and there at wide intervals, there is nothing of a mountainous nature to be seen. No apparent cause exists for any deflection of the plumb-line.—S.G.B.]

Geodetic Latitude of the Astronomical Station = 26° 39' 52"·74

141. Chandaos Tower Station (No. XXXVI of the Great Arc Meridional Series—Section 24° to 30°; volume IV of the *Account of the Operations &c.*) is built on a high bank of accumulated sand about 400 yards from the village of that name in pargana Khair of the Aligarh district. The adjacent villages are—Umri 5·9 miles, S.W., and Elampur 2·4 miles, N.W.

The station consists of a perforated pillar of masonry, 40 feet high and having a mark-stone on the ground floor.

[The Astronomical Station is 1,272 feet east of the Trigonometrical Station and is not more than four inches out of the prime vertical, the latitudes of the two points may therefore be considered identical.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station = 28° 5' 1"·59

142. Chandipur Tower Station (No. XXII of the East Coast Series, volume VI of the *Account of the Operations &c.*) which was on a sand-hill near the sea coast, about 6 miles E.S.E. of Balasore, was reported by Lieut. E. A. Tandy R.E. in 1898 to have entirely disappeared. There are no traces left of the station except broken pieces of masonry.

[The Latitude pillar was erected on the sand-cliff 151 feet to the west of the assumed station. The cliff is about 34 feet high and has a slope of about  $60^\circ$ , and its foot is just lapped by the sea at high water. The pillar is about 24 feet back from the face of the cliff. Except for the effect of the Bay of Bengal to the S.E., no local attraction is to be anticipated. There is a levelling bench-mark 50 yards south of the Latitude pillar marked G. T. S. B. M.—E.A.T.]

The Latitude of the Astronomical Station is assumed to be the same as that of the old Trigonometrical Station.  
Geodetic Latitude of the Astronomical Station =  $21^\circ 26' 36''\cdot99$

143. Chanduria (Chendoria) Tower Station (No. XXXVIII of the Calcutta Meridional Series, volume VIII of the *Account of the Operations &c.*) is situated about 300 yards N. of the nearest portion of the scattered village of this name,  $4\frac{1}{4}$  miles E. of Lochan village near the intersection of the roads from Raiganj and Dinajpur; thána Pirganj, pargana Khára, district Dinajpur. The station consists of a solid tower of sun-dried bricks, enclosing a central pillar of masonry 20·75 feet in height and is marked in the usual manner. The azimuths and perambulated distances of the circumjacent villages are:—Brijgaon  $316^\circ 31'$ , mile 0·77; Karnai  $226^\circ 28'$ , miles 1·24; Málancha  $158^\circ 41'$ , miles 1·07; and Mahádebpur  $116^\circ 11'$ , mile 0·63.

[The Latitude pillar is 45 feet east of the Trigonometrical Station. There is no reason to suppose any local influences disturbing the direction of the plumb-line. Half the Trigonometrical pillar remains standing, protected by an earthen mound. The "half way" mark is in good preservation. The latter was covered by a small pillar 2 feet square in section and about 2 feet high. The whole was then covered by earth.—H.M.C.]

Geodetic Latitude of the Astronomical Station =  $25^\circ 44' 27''\cdot47$

144. Chánga Hill Station (No. LXXX of the Karachi Longitudinal Series, volume III of the *Account of the Operations &c.*) is situated on a sand-hill bearing that name in that portion of the Thar, or Little-desert, appertaining to Bhúj. The town of Chelar lies to the east at a distance of about  $3\frac{1}{2}$  miles. The pillar is solid, and 3 feet high. Mark-stones were embedded at top and bottom, and 2 feet above the latter.

[Though the Trigonometrical Station is described in Synoptical Volume III as having entirely disappeared, a portion of the original pillar, 2 feet in height, was found some 3 feet below the surface of the sand. The Latitude pillar is built over the Trigonometrical Station. There is no reason to suppose any deflection of the plumb-line.—H.M.C.]

Geodetic Latitude of the Astronomical Station =  $24^\circ 58' 47''\cdot00$

145. Chaniána Hill Station [No. III (Siniána) of the Abu Meridional Series, volume XIV of the *Account of the Operations &c.*] is situated in the lands of the village Chaniána, pargana and state Pálanpur. The station consists of a platform, enclosing a solid, circular and isolated pillar of masonry: there are two marks, one engraved on the rock *in situ* and the other 3 feet above it in the upper surface of the pillar. The directions and distances of the circumjacent villages are:—Chaniána N.W. by W., mile 1; Gola N. by W., miles 2; Vansol E. by N., miles 2; Dhota S., miles  $2\frac{1}{4}$ ; and Varvadia S.W., miles 2.

[The Astronomical Station at Chaniána is built on the prime vertical of the Trigonometrical Station of Chaniána, and about 400 yards east of the latter. It is on the summit of a conspicuous sand heap. The southern horizon is broken by no hills: a few small conical heaps of rock lie S.E. and S.W. but the whole land to the south is flat. The Aravalli range commences 5 miles N.E., Mount Abu is 30 miles north, and Jairáj hill 20 miles N.W. The Aravallis are considerable hills and northerly attraction is to be expected.—S.G.B.]

Geodetic Latitude of the Astronomical Station  $24^\circ 6' 36''\cdot64$

146. Charaldánga Tower Station (No. XXVII of the Calcutta Meridional Series, volume VIII of the *Account of the Operations &c.*) is situated in thána Gumashtapur, pargana Paltapur, district Malda. It is on the Barind, in the middle of a patch of thick thorny jungle, about  $6\frac{1}{2}$  miles E. by N. of the large village of Bangabári on the left bank of the Mahánada river and  $5\frac{1}{2}$  miles N.W. of Chotipur on the high road from Godagári to Dinajpur. The station consists of a square solid tower of sun-dried bricks, enclosing a central pillar of masonry. The azimuths and perambulated distances of the circumjacent villages are:—Charaldánga  $67^\circ 10'$ , mile 0·30; Rámkandar  $119^\circ 51'$ , mile 0·64; Básudebpur  $193^\circ 18'$ , mile 0·37; and Sujanagar or Magrakandar  $267^\circ 52'$ , mile 0·44.

[The Latitude pillar is 220·8 feet east of the Trigonometrical Station and in the true prime vertical of the same. The surrounding country is undulating, covered with patches of thorn jungle. To the west there is a lowlying bit of ground

of considerable extent. There is however no apparent cause of any appreciable local disturbance of the direction of the plumb-line. The lower mark of the Trigonometrical Station is in satisfactory preservation, though the tower itself has fallen and now forms an earthen mound some 14 feet high.—U.M.C.]

Geodetic Latitude of the Astronomical Station =  $24^{\circ} 52' 43'' \cdot 95$

147. Colába Latitude Station is 7 feet west and 9 inches south of the Bombay Longitude Station (*vide* volume IX of the *Account of the Operations &c.*). The Longitude Station is situated in the compound of the Colába Observatory, 55 feet north, and 53 feet east of Colába s., a secondary station of the Bombay Longitudinal Series.

[The Latitude Station consists of a circular masonry pillar 3 feet in diameter and 2 feet 6 inches in height.—G.P.L.C.]

Geodetic Latitude of the Longitude Station =  $18^{\circ} 53' 49'' \cdot 49$   
Reduction to Latitude Station =  $- 0 \cdot 01$

Geodetic Latitude of the Latitude Station =  $18 \ 53 \ 49 \cdot 48$

148. Cuttack or Barabati Hill Station (No. XXXV of the East Coast Series, volume VI of the *Account of the Operations &c.*) is situated on a mound or bastion in the old ruined fort of Cuttack. The station is marked by a stone embedded in the surface of a paka platform.

[The Astronomical Station is on a large mound or hillock in the old fort and within 100 yards of Cuttack Club. There are a few small hills 12 miles to the north, and some more considerable ones 10 to 50 miles in the same direction; the whole of these might account for a northerly attraction of  $1''$ . The sea is 50 miles distant to the S.E. The Latitude was observed from the Trigonometrical Station.—E.A.T.]

Geodetic Latitude of the Astronomical Station =  $20^{\circ} 29' 0'' \cdot 68$

149. Daiádhari Hill Station (No. II of the Great Arc Meridional Series, Section  $24^{\circ}$  to  $30^{\circ}$ , volume IV of the *Account of the Operations &c.*) is situated on a low detached hill in the Gwalior territory. The adjacent places, with their distances and directions are:—Sadhora, a town and railway station, about 4 miles, S.W.; and the large village and railway station of Puchar about  $6\frac{1}{2}$  miles, S.E. In 1898 the pillar of the Trigonometrical Station was found to have been destroyed; it had been dug out and the mark-stones removed or displaced. The well surrounding the pillar was however intact and it was assumed that the centre of this well would define with sufficient exactness the position of the old mark. A mark-stone was consequently placed at the bottom of the well and adjusted centrally and then a paka pillar 3 feet 6 inches in diameter was built to the level of the surface of the platform, making it 5 feet high, and a second mark-stone was placed on the top of the pillar in the normal of the lower one.

[The station stands on the highest point on an unimportant isolated hill about 100 feet above the surrounding plain. The top is fairly level and about 50 yards wide by 150 long, the direction of the length being north and south. The station is at the northern edge. Similar small hills are scattered over the country at intervals, the nearest being about  $1\frac{1}{2}$  miles from the station. The Astronomical Station consists of the usual circular pillar suitable for the zenith sector, and is situated 58 feet 6 inches west and 2 feet 4 inches north of the Trigonometrical Station.—G.P.L.C.]

Geodetic Latitude of the Trigonometrical Station =  $24^{\circ} 38' 17'' \cdot 57$   
Reduction to Astronomical Station =  $+ 0 \cdot 02$

Geodetic Latitude of the Astronomical Station =  $24 \ 38 \ 17 \cdot 59$

150. Dalea Hill Station (No. XII of the Biláspur Meridional Series, volume VI of the *Account of the Operations &c.*) is situated in the lands of Ámbáli, pargana Kenda, district Biláspur of the Central Provinces. It is on a small isolated peak, locally so named, which overlooks the plains and is separated from the great mass of hills to the north by a distance of about 10 miles. The station consists of a solid pillar of masonry, having two marks, one in the upper surface and the other 4 feet below it on the rock *in situ*. The azimuths and estimated distances of the circumjacent villages are:—Nawágaon  $175^{\circ} 54'$ , miles 1.75; Billíbañ  $227^{\circ} 9'$ , miles 2; and Ámbáli  $321^{\circ} 48'$ , miles 2.

[Dalea is on a steep pointed hill rising 600 or 700 feet above the plain. It is amongst the southernmost of the masses of hills which stretch all across the country to the north. A local attraction of about  $5''$  N.W. might be expected. The Astronomical Station was coincident with the Trigonometrical Station.—E.A.T.]

Geodetic Latitude of the Astronomical Station =  $22^{\circ} 19' 33'' \cdot 62$

151. Dánapa Hill Station (No. XIV of the Madras Meridional and Coast Series, volume XIII of the *Account of the Operations &c.*) is situated in the lands of the village Görépád, taluk Narsaraópet, district Kistna. It is on a range of hills lying nearly N. and S. and about  $1\frac{1}{2}$  miles W. of the high

road from Madras to Hyderabad. The station is not on the highest peak of the hill, that being taken up by a place of worship. The station consists of a solid pillar of masonry having two marks, one engraved on the rock *in situ* and the other 1 foot above it. The directions and distances of the circumjacent villages are:—Kappērapād E., miles  $1\frac{3}{4}$ ; Vaidana N.E., miles  $2\frac{3}{4}$ ; Kukutlapalle N., miles 2; Gōrēpād W. by S., miles  $2\frac{1}{2}$ ; and the place of worship on the summit of the hill is N. by W. at a distance of about 150 to 200 yards.

[The Astronomical Station is built in the prime vertical of the Trigonometrical Station, 1 mile and 44 yards to the east of it. It is about a mile to the west of the village of Kapurpad through which the main road runs. A number of rather high hills belt the horizon on every side but in such a way as not to cause deviation of the plumb-line in the meridian.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $15^{\circ} 56' 0'' \cdot 14$

152. Dargawa Hill Station (No. II of the Budhon Meridional Series, volume VII of the *Account of the Operations &c.*) is situated in the lands of Dargawa village; pargāna Baldeogarh of the Orchha or Tehri State. It is on steep rocky ridge running nearly north and south, at the northern foot of which is the village Dargawa 0·4 mile from the station. The distances and directions of other surrounding villages are:—Parra 0·3 mile, N.W.; Rasoi 1 mile, N.N.W.; Bhadaura 1·4 miles, S.S.W.; and Magarkhera 1·6 miles, E.S.E. The station is marked on the rock *in situ*.

[The Astronomical Station is built in the prime vertical of the Trigonometrical Station and 1369 feet east of it. The Trigonometrical Station is on a steep rocky ridge rising abruptly 500 feet above the surrounding plain, the Latitude pillar being at the foot of the slope. The local masses are not capable of producing any deflection of the plumb-line of appreciable amount. The small attraction that may exist should be to the S.W.—H.M.C.]

Geodetic Latitude of the Astronomical Station =  $24^{\circ} 37' 13'' \cdot 21$

153. Dariápur Tower Station (No. VIII of the East Coast Series, volume VI of the *Account of the Operations &c.*) is situated on an elevated sand-ridge about 300 yards from the village of Dariápur-Bamaria which bears  $137^{\circ} 30'$ , in pargāna Báljōra, district Midnapore. The road from Contai to Kedgri passes about 3 miles to the west of the station, and the Rasalpur ferry is about 3·25 miles N.W. The bearings and distances of the surrounding villages are:—Partábpur  $50^{\circ} 0'$ , mile 0·6; and Gopínáthpur  $340^{\circ} 0'$ , mile 0·3. A temple, which stands on the same ridge as the station, bears  $251^{\circ} 40'$  and is distant 0·4 of a mile. The station consists of a solid pillar of masonry, having a mark-stone at the bottom.

[The Astronomical Station is on the sea dyke 200 yards east of Dariápur inspection bungalow. The coast of the Bay of Bengal lies 2 miles S.E. and 3 miles S. Beyond the vicinity of the sea there is no fact likely to cause local attraction. The Latitude pillar is to the east of the Trigonometrical Station 28 feet from it, and in the prime vertical. There seems absolutely no shadow of doubt as to the identity of the Trigonometrical Station, but the pillar is white-washed, and there is no mark on the top and it is not the right height. Its height is 13 feet from bottom mark.—E.A.T.]

Geodetic Latitude of the Astronomical Station =  $21^{\circ} 47' 27'' \cdot 95$

154. Darutippa (also called Mangalapápēmtippa) Station (No. XXV of the Madras Meridional and Coast Series, volume XIII of the *Account of the Operations &c.*) is situated in the lands of the village of Chalamchērla, taluk Kandukur, district Nellore. It is about  $4\frac{1}{2}$  miles S. by E. of the village of Gudlūr, and  $6\frac{1}{2}$  miles W.S.W. of Tēttu on the road from Madras to Ongole. The directions and distances of the circumjacent villages are:—Pēddavaram S.W. by S., miles  $1\frac{1}{4}$ ; Chalamchērla S.E., miles 3; Ammavaripālēm W. by N., miles  $1\frac{1}{4}$ ; and Potlūr N.E. by N., miles 3.

[The Astronomical Station is built in the prime vertical of the Trigonometrical Station, 1430 yards to the west of it and about  $\frac{1}{2}$  a mile to the east of the village Ammavaripālēm which lies close to a large tank. The surrounding country is very flat and no deviation is to be anticipated. The Trigonometrical Station had fallen into very bad repair in 1891.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $15^{\circ} 0' 36'' \cdot 47$

155. Decsa Longitude Station (*vide* volume IX of the *Account of the Operations &c.*) is situated in the compound of the Telegraph Office. It is 89 feet S. and 56 feet W. of Decsa Telegraph Office s., a secondary station of the Abu Meridional Series.

[The Latitude Station at Decsa is coincident with the Longitude Station and 20 feet from the eastern corner of the new Telegraph Office. The Aravalli Hills lie 40 miles east: Mount Abu is 20 miles north-east, and a few isolated rocky hills protrude here and there: otherwise the whole country is a flat desert.—S.G.B.]

Geodetic Latitude of the Latitude Station =  $24^{\circ} 15' 29'' \cdot 85$

156. Dehra Dún Base-line East End Station [No. (IX) of the Great Arc Meridional Series, Section 24° to 30°, volume IV of the *Account of the Operations &c.*] is situated on the extremity of one of the spurs of the Gháti or Siwalik range of hills in the district of Dehra Dún. The nearest village is Mohabawála, about a mile to the south-east. The Ásan river winds round the foot of the spur, and one branch of it takes its rise in a ravine about 100 yards to the westward of the station. For its protection and to facilitate identification, a tower was built over the masonry platform with sides parallel or perpendicular to the line of the base, and with an arched passage 5 feet wide and 6 feet high, to allow of access to the mark-stones, should the base be remeasured at any future time. The mark in the stone on the summit of the tower is 8·71 feet above Colonel Everest's upper mark, and consequently 1967·78 feet above the mean sea-level of Karachi harbour.

[The Astronomical Station consists of a circular masonry pillar 3 feet in diameter, and 2 feet 6 inches in height. Its upper surface is level with the ground. It is situated on the prime vertical of the Base-line station and 22 feet 3½ inches to the west of it. The Siwalik hills rise immediately to the south of this station and probably tend to reduce the effect of the attraction of the Himalaya.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station = 30° 17' 7"·35

157. Dehra Dún Longitude Station (*vide* volume XV of the *Account of the Operations &c.*) is situated in the north-eastern portion of the Survey of India Office compound, 33 feet 6½ inches north of the Haig Observatory, 43 feet 6 inches from the northern boundary wall measured on the ray to the Mussooree eastern meridian mark, and 628 feet 9 inches due east of the smaller Photo-heliograph Observatory called Dehra Dome Observatory T. S. (new) in Synoptical Volume II.

Dehra Dún (Haig Observatory) Latitude Station is 66 feet 5 inches east of the Haig Observatory. It is 39 feet 11½ inches south and 89 feet 8 inches east of the Dehra Dún Longitude Station.

Geodetic Latitude of the Longitude Station = 30° 19' 29"·13  
Reduction to Latitude Station = — 0·40

Geodetic Latitude of the Latitude Station = 30° 19' 28"·73

158. Dera Dín Panáh Platform Station (No. CXII of the Great Indus Series, volume III of the *Account of the Operations &c.*) is situated on the top of the N.W. bastion of the old kacha fort so called; thána Dera Dín Panáh, tahsíl Adúkot, district Muzaffargarh. The pillar, 6 feet deep, was countersunk into the bastion, and a mark-stone placed at its upper surface.

[The Astronomical Station was 300 feet due west of the Trigonometrical Station. The Suleimán Mountains are visible all along the horizon from N.W. to S.W. Slight northerly attraction is to be expected.—S.G.B.]

Geodetic Latitude of the Astronomical Station = 30° 34' 1"·87

159. Dhauleshvar Hill Station (No. XXVII of the Bombay Longitudinal Series, volume XII of the *Account of the Operations &c.*) is situated on the roof of the temple of this name on a range of hills running E. and W.: it is about 2¼ miles E.N.E. of the Borghát, and on the high road from the town of Jejuri to the railway station of Uruli on the G. I. P. line. The station is on the boundary of the villages of Dalimb and Amla of talukas Purandhar and Bhimthadi, district Poona. The directions and distances of the circumjacent villages are:—Dalimb N.N.W., miles 1½; Valti W. by N., miles 3¼; Vaghapur S.W., miles 3¼; Amla S. by E., miles 1½; and Malsiras E.S.E., miles 4¾.

[The Astronomical Station was built in the prime vertical about 25 feet to the west of the Trigonometrical Station. The hill is the highest point of a range which runs almost exactly east and west. The valley to the north is about 1100 feet below the station; while that to the south is only some 600 feet below, and besides this there are other hills to the south and none of any consequence to the north; so that it appears probable that there may be some deviation of the plumb-line to the south.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station = 18° 25' 41"·64

160. Dhúlipalla Station (No. VII of the Madras Meridional and Coast Series, volume XIII of the *Account of the Operations &c.*) is situated in the lands of the village of Dhúlipalla, taluk Sattēnapalle, district Kistna. It is on high ground in the midst of fields and lies about 4¾ miles N.W. by W. of the taluk town of Sattēnapalle on the high road from Hyderabad to Guntúr, and the same distance N.N.W. of the large village of Mandala. The directions and distances of the circumjacent villages are:—Bhrugubanda N. by E., miles 1½; Dhúlipalla S. by W., miles 1½; Makkapád

N.W., miles  $2\frac{1}{4}$ ; Rēddigūdēm W. by N., miles  $2\frac{1}{2}$ ; and Tōndapi S.W. by S., miles  $3\frac{1}{3}$ . The station consists of a platform of stones and earth enclosing a solid, circular and isolated pillar of masonry in which are three mark-stones, one embedded in the soil and two others at 3 and 5 feet above it.

[The Latitude pillar is built on the Trigonometrical Station. The surrounding country consists of a series of undulations. There is a range of hills, running S.W. to N.E. and terminating at a distance of 15 miles. The nearest point is about 8 miles off. There is another range running in the same direction—bearing S.E. from the station at a distance of 12 miles and there is a small isolated hill due south 15 or 20 miles off. There is probably a little northern attraction.—J.E.]

Geodetic Latitude of the Astronomical Station =  $16^{\circ} 25' 56''\cdot75$

161. Didāwa Hill Station (No. LXII of the Karachi Longitudinal Series, volume III of the *Account of the Operations &c.*) is situated on a sand-hill in the Thar or Little-desert, and distant from the hamlet of Didāwa  $\frac{3}{4}$  of a mile. It is in the Jodhpore territories.

[The Astronomical Station is directly over the Trigonometrical Station of the same name. The nearest village is Bidabav,  $1\frac{1}{2}$  miles to N.E. The country is rugged in appearance—the sand-hills being steep and much eroded by water. There are no grounds for expecting a deflection of the plumb-line from local causes. The Trigonometrical pillar had entirely disappeared, the bottom mark and foundation being found with difficulty.—H.M.C.]

Geodetic Latitude of the Astronomical Station =  $24^{\circ} 51' 19''\cdot36$

162. Dīwai Hill Station (No. XXXIII of the Jabalpur Meridional Series, volume VI of the *Account of the Operations &c.*) is situated in the lands of the village of Pomūrna; pargana Ghātkūl, tahsīl Mūl, district Chānda. The village of Kauarji lies about 4 miles W. by N. The station consists of a solid pillar of masonry having two marks.

[The Latitude pillar is built on the Trigonometrical Station which is on the top of a hill some 900 feet high. The hill is so thickly covered with a dense bamboo jungle that it is difficult to see the features of the surrounding country. It is certain that there are no hills of any extent either to the north or south and as far as can be judged, the small hills are about equally distributed so that no local attraction need be expected.—J.E.]

Geodetic Latitude of the Astronomical Station =  $19^{\circ} 49' 32''\cdot57$

163. Gudali Hill Station (No. XXXVIII of the Madras Meridional and Coast Series, volume XIII of the *Account of the Operations &c.*) is situated in the lands of the village of Gudali, taluk Gudur, district Nellore. It is on an isolated rocky hill lying about  $\frac{1}{2}$  a mile from the left bank of the Swarnamukhi river and immediately N. of the village of Gudali; about one mile S.W. of the high road from Dugarazpatanam. The directions and distances of the circumjacent villages are:—Kota N.E. by E., miles  $2\frac{1}{2}$ ; Kurrugōnda W., miles 4; Kasipuram S.E., miles  $1\frac{3}{4}$ ; Razupālēm W. by N., mile  $\frac{1}{2}$ ; and Tinnelapūdi E.S.E., miles  $1\frac{1}{4}$ . The station consists of a platform of stones and earth enclosing a solid, circular and isolated pillar of masonry, having two marks, one engraved on the rock *in situ* and the other 6 feet above it.

[The Astronomical Station coincides with the Trigonometrical Station and is situated on the highest point of a hill some 300 feet higher than the surrounding country. This highest point is not over the centre of the mass of the hill but to the north-west of it, so that a slight deviation to the south may possibly exist. The surrounding country is flat or gently undulating for miles so that no other source of deviation is apparent.—G.P.L.C.]

• Geodetic Latitude of the Astronomical Station =  $14^{\circ} 1' 9''\cdot45$

164. Gūrmi Tower Station (No. XVII of the Budhon Meridional Series, volume VII of the *Account of the Operations &c.*) is situated on a bastion at a northern angle of the mud fort attached to the village of Gūrmi which lies between the Sānichri hills and the Chambal river: in the Gwalior State. The distances and directions of the surrounding villages are:—Silauli 1·6 miles, N.W. by W.; Kalyānpura 1·6 miles, S.W. by W.; and Gopālpura 1·4 miles, E. by S.

[The Latitude pillar is 920 feet due west of the Trigonometrical Station. The Trigonometrical Station originally consisted of a tower, with upper and lower marks, on the northern bastion of the mud fort in Gūrmi village. Both tower and bastion have been destroyed by the action of the weather—the tower completely so—so that in time the lower mark became exposed. The short pilaster like stone on which this mark had been cut, originally buried with its longer axis vertical, had, as the bastion crumbled away, fallen to one side. It was however re-erected by a Patwari about 1898. It is evident, however, that if the tower had been in the centre of the bastion, the error in the present position of the stone cannot be more than 1 foot in any direction. Local disturbances of the plumb-line either in meridian or in prime vertical are not to be expected.—H.M.C.]

Geodetic Latitude of the Astronomical Station =  $26^{\circ} 36' 3''\cdot63$

165. Háthbena Hill Station (No. XLIII of the Biláspur Meridional Series, volume VI of the *Account of the Operations &c.*) is situated in the lands of the village of Kotgaon, pargana Ráigarh of the Jaipur State. It is on a long, high, isolated hill lying east and west. The directions and estimated distances of the circumjacent villages are:—Kotgaon E., about 2·5 miles; the town of Ráigarh N.E., about 3·75 miles; Birsári village S.E., about 3 miles; and the deserted village of Háthbena N.W., about 2 miles. The boundary between Jaipur and Bastar passes about 4 or 5 miles to the west of the station. The station consists of a solid pillar of masonry having two marks, one on the upper surface and the other engraved on the rock *in situ*.

[The Astronomical Station coincides with the Trigonometrical Station. It is on the highest of a small group of low hills and is about 500 feet above the surrounding plain. There is no apparent reason to expect any particular local attraction.—E.A.T.]

Geodetic Latitude of the Astronomical Station = 19° 51' 42"·34

166. Jalpaiguri Station (a secondary station of the Assam Longitudinal Series), is situated on the roof of the Deputy Magistrate's kachahri, a paka building on a piece of land between the Tista and Kulla rivers. The mark is 36 feet 4 inches, 26 feet 6 inches, 33 feet 6 inches and 22 feet 3 inches distant respectively from N.W., S.W., N.E. and S.E. corners of the roof.

[The Latitude Station is 86·5 feet east of the Longitude Station (*vide* volume X of the *Account of the Operations &c.*) and 228 feet north of the Trigonometrical Station. The station consists of an isolated pillar of masonry, 3 feet in diameter, the top of which is flush with the ground surface. The Trigonometrical Station is in perfect preservation.—H.M.C.]

Geodetic Latitude of the Trigonometrical Station = 26° 31' 15"·13  
Reduction to Latitude Station = + 2·26

Geodetic Latitude of the Latitude Station = 26 31 17·39

167. Jambo Hill Station (No. XXVI of the Jodhpore Meridional Series, volume IVA of the *Account of the Operations &c.*) is situated in the lands of the village of Naneo, pargana Phalodi of the Jodhpur territories. It is distant 2·4 miles from the village of Jambo, on a long sand-ridge which runs in a N.E. and S.W. direction. The azimuths and distances of the circumjacent places are:—Phalodi town 45°, miles 13·75; Sawanti village 76° 30', miles 3; and Báp village of the Jaisalmer territories 125°, miles 12·2. The station consists of a solid pillar of masonry, having three mark-stones, one in the upper surface of the pillar, the second at the bottom of the pillar and the third at the bottom of the foundation.

[The Astronomical Station is coincident with the Trigonometrical Station of Jambo. It is situated on a small sand-ridge in the midst of a flat sandy desert: with the exception of small sand-hills, the whole desert is a plain as far as the eye can reach. No apparent cause exists for deflection of the plumb-line.—S.G.B.]

Geodetic Latitude of the Astronomical Station = 27° 16' 28"·88

168. Kaliánpur Hill Station [No. (VII) of the Great Arc Meridional Series, Section 24° to 30°, *vide* Base-line figures in volume III of the *Account of the Operations &c.*] is situated in the lands of the village of Kaliánpur in pargana Sironj of the Tonk State. It is on a flat, elevated ridge of iron-clay formation, locally called Bhuri Tori, which skirts the Sironj valley to the S.W. and N. The station consists of a solid pillar of masonry 2 feet high, containing mark-stones at top and bottom and enclosed in a platform of solid masonry 14½ feet square.

[The Trigonometrical Station, which is 1,765 feet above mean sea-level, is on the highest of a series of rolling hills or downs which form the eastern edge of an extensive plateau about 170 feet higher than the plain to the east. The edge of the plateau runs north and then north-east and disappears in the distance; it is somewhat higher than the central parts and more undulating. The town of Sironj lies about 2½ miles to the south-east. The Latitude pillar is situated on the east side of the Trigonometrical Station on an Azimuth of 270° 4' 38" and at a distance of 39 feet 7 inches, so that the latitudes of the two may be considered identical.—G.P.L.C.]

The adopted value of latitude (*vide* Chapter IV) is 24° 7' 11"·26

169. Kámkhera Hill Station [No. (IV) of the Karachi Longitudinal Series, volume III of the *Account of the Operations &c.*] is situated in the lands of the village of Imlani, in pargana Sironj of the territories of the Nawab of Tonk. The circumjacent villages, with their distances and directions are:—Imlani 2 miles, N.W.; Kámkhera 1½ miles, W.; Ladhora about 2 miles, N.; and Kua about 2 miles, S. The pillar is solid, and 10 feet high. It has a mark-stone at top, another at bottom, and two others at distances of 2 and 6 feet respectively above the latter.

[The Trigonometrical Station is on a flat-topped hill near the southern end of the Kaliánpur plateau. Its height is 1,780 feet above mean sea-level. The Latitude pillar is situated in the prime vertical of the Trigonometrical Station and 48 feet 11 inches east of it.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $23^{\circ} 59' 44'' \cdot 93$

170. Kanheri Hill Station (No. XVIII of the Bombay Longitudinal Series, volume XII of the *Account of the Operations &c.*) is situated on a knoll of the Bálegghát range, about  $\frac{1}{3}$  of a mile N.W. of the road from Sávargaon to Vási, and  $4\frac{3}{4}$  miles N.E. by E. of the large village of Bhum. It is in the lands of the village of Kanheri, district Naldurg, Nizam's territory. The directions and distances of the circumjacent villages are:—Kanára N.E. by N., miles  $1\frac{1}{2}$ ; Sonágiri W. by N., miles 4; Pardi E. by N., miles  $2\frac{3}{4}$ ; Hadangiri S.S.W., miles 2; and Bonágiri W. by N., miles  $3\frac{1}{2}$ . The station consists of a perforated pillar of masonry 4·9 feet high and has an aperture giving access to the lower mark.

[The Astronomical Station is coincident with the Trigonometrical Station. It is situated on a high point of the edge of the great raised plateau which extends to the north-east. This edge is a very marked feature, being some 800 feet above the country to the S.W. and rises rather abruptly. Its general direction is from N.W. to S.E. and it is possible therefore that, there being so much more elevated ground to the north than to the south, there may be some deviation of the plumb-line in the former direction. So far as immediate surroundings are concerned, the station is well placed.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $18^{\circ} 29' 30'' \cdot 75$

171. Karía Hill Station (No. L of the Biláspur Meridional Series, volume VI of the *Account of the Operations &c.*) is situated in the lands of the village of Tangapal which lies about 2·5 miles N.; pargana Ambra of the Bastar State. It is on a well known hill of that name forming the highest of a series of undulations on the north bank of the Indrávati. The pillar is solid and contains two marks, the upper 2·96 feet above the lower which is engraved on a block of stone imbedded in the foundation. The azimuths and distances of the circumjacent villages are:—Dasapal  $104^{\circ}$ , miles 2·76; and Auli  $241^{\circ}$ , miles 3·37. The boundary between Jaipur and Bastar runs through the centre of the village of Auli which is thus partly subject to the jurisdiction of Jaipur and partly to that of Bastar.

[The Astronomical Station is on a low hill in an undulating country, and is identical with the Trigonometrical Station. The Eastern Gháts are nearly 40 miles distant and might account for a local attraction of  $1''$  to the S.E.—E.A.T.]

Geodetic Latitude of the Astronomical Station =  $19^{\circ} 12' 5'' \cdot 98$

172. Kárethol Hill Station (No. CIV of the Karachi Longitudinal Series, volume III of the *Account of the Operations &c.*) is situated in the Karachi Collectorate of Sind, on the highest part of a hill of the same name. The pillar is 3 feet high.

[The Latitude pillar is  $310\frac{1}{2}$  feet due east of the Trigonometrical Station which is on the highest point of a small hill, 3 miles S.S.W. of Janabad Railway Station, N.W. Railway. A deflection of not more than  $2''$  to the N.N.W. might be caused by the lower Baluchistan hills, the outer ranges of which are some 20 miles distant.—H.M.C.]

Geodetic Latitude of the Astronomical Station =  $24^{\circ} 53' 46'' \cdot 69$

173. Kaulia Hill Station is situated on the extreme summit of the range known locally as Kaulia. This range forms part of the Kukani hill and lies due west of the Resident's bungalow at Kukani. The mark is about  $3\frac{1}{2}$  hours sharp walk from the Residency in Katmandu. The bearings of the adjacent places are:—N.W. corner of Prime Minister's House (new)  $324^{\circ} 5'$ , Katmandu Clock Tower  $324^{\circ} 15'$ , Kukani Bungalow  $90^{\circ} 55'$ , Budhnath Pagoda  $307^{\circ} 55'$  and Rocko  $12^{\circ} 30'$ . A wooden peg, into the centre of which a nail has been driven, marks the site of observation. The mark has been covered with an old tin and surrounded by large rocks forming a cairn 6 feet in diameter and about 7 feet high. The position of the station was determined from observations to known peaks.

Captain Wood's "*Report on the Identification and Nomenclature of the Himalayan Peaks as seen from Katmandu, Nepal*" published in 1904, gives the geodetic co-ordinates of Kaulia as follows:—

Latitude  $27^{\circ} 48' 58'' \cdot 6$

Longitude  $85^{\circ} 16' 47'' \cdot 9$

174. Khankharia Station (No. LI of the Karachi Longitudinal Series, volume III of the *Account of the Operations &c.*) is situated on a sand-hill  $1\frac{1}{4}$  miles from Lelawa village, which is on the telegraph line from Deesa to Umarnkot. The station is in Pálanpur State. The large village of Ninawa lies about  $3\frac{1}{4}$  miles to the N.E., and Baja village is distant about  $2\frac{1}{4}$  miles. The station consists of a

id pillar of masonry 8 feet high, having five marks, one at its base, and the others 2, 6, 7 and 8 feet respectively above it.

[The Astronomical Station is on the prime vertical and 40 feet west of the Trigonometrical Station. It is about 30 miles from Deesa. The out-skirts of the Jeypore hill tracts are some 60 miles to the N.E. The country is one of undulating sand-hills. There is no apparent local cause of deflection of the plumb-line at this station.—H.M.C.]

Geodetic Latitude of the Astronomical Station =  $21^{\circ} 36' 56''.19$

175. Khánpisura Hill Station (No. XXI of the Bombay Longitudinal Series, volume XII of the *Account of the Operations &c.*) is situated in the lands of the village of Khadgaon, taluka Shrigonda of the Ahmednagar district, on a hill about  $1\frac{1}{2}$  miles S.W. of the village of Khángad. The station consists of a solid pillar of masonry having two mark-stones, one at the ground level and the other 1 foot  $7\frac{1}{2}$  inches below it. The directions and distances of the circumjacent villages are:—Vadghula N., miles 2; Khadgaon E.N.E., miles 2; Bhanggaon S.W., miles  $3\frac{3}{4}$ ; and Dhorja W.S.W., miles  $3\frac{3}{4}$ .

[The Astronomical Station is coincident with the Trigonometrical Station. It is situated on a flat-topped hill which forms the eastern flank of a pass through a range which runs rather irregularly to the N.W. A considerable spur runs out to the north, while to the south the fall is abrupt. The hills to the S.E. on the other side of the pass are of much the same height. The level of the country is somewhat higher towards the north than towards the south, and this together with the spur to the north, mentioned above, may cause some deviation to the north.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $18^{\circ} 45' 30''.65$

176. Khirsar Hill Station (No. XLIV of the Jodhpore Meridional Series, volume IVA of the *Account of the Operations &c.*) is situated in the lands of the village of Khirsar in pargana Pungal of the Bickaneer territories. The hill slopes gently from the south and terminates abruptly to the north being there 186 feet above the adjacent plain. The path from Dattohar to Pungal runs south of the hill. The pillar, which is surrounded by a platform of stones and sand, is solid and 5.15 feet high with a foundation one foot deep, and has three mark-stones, one at the top of the foundation, a second 2.54 feet above it and the third 2.60 feet above the second, flush with the top of the pillar. The approximate directions and distances of the circumjacent villages are:—Dattohar S.W. by S., miles 10.05; Pungal E., miles 9.5; Ramra S., miles 6 nearly; and Khirsar E. by S., miles 3.37.

[The hamlet of Khirsar, mentioned by Colonel Rogers in 1874, has disappeared; there was no village within a day's march, and water had to be brought daily from Pungal, a distance of 11 miles. Perfectly flat sandy desert; plumb-line unaffected by hills. The Astronomical Station was coincident with the Trigonometrical Station.—S.G.B.]

Geodetic Latitude of the Astronomical Station =  $28^{\circ} 29' 40''.91$

177. Khori Tower Station (No. XCI of the Karachi Longitudinal Series, volume III of the *Account of the Operations &c.*) is situated in the Hyderabad Collectorate of Sind at about 1 mile from the largest of the three villages after which it is named. The village of Kariana is distant  $2\frac{1}{2}$  miles, at an azimuth of  $350^{\circ}$ , and that of Rain 1.3 miles nearly due N. The pillar is 15 feet high, and has five mark-stones imbedded in it, one at level of foundation, the others at 6, 12, 14 and 15 feet respectively above it.

[The Latitude pillar is 106 feet due west of the Trigonometrical Station. It is situated on the Sind plains  $5\frac{1}{2}$  miles N.W. from Dádáh village. The Trigonometrical Station was in good condition in 1901. There is no apparent cause for any deflection of the plumb-line.—H.M.C.]

Geodetic Latitude of the Astronomical Station =  $25^{\circ} 0' 31''.53$

178. Khundábolo Hill Station (No. XLI of the East Coast Series, volume VI of the *Account of the Operations &c.*) is on the summit of the highest of the elevated and extensive hilly tract lying to the west of the Chilka lake and dividing Gumsúr from Bhánpur. The hill on which the station is situated belongs partly to the former and partly to the latter; the part whereon the station is, appertains to the village of Korácháli in the Gumsúr estate, district Ganjam. The country round is covered with heavy tree jungle and is very thinly populated; such small hamlets as exist are inhabited chiefly by Khonds. The nearest village is Kalsúli in the Gumsúr estate and it is distant about 10 miles to the north-west. The ascent which is long and easy, commences from the small village of Anpúrná, distant about 5 miles, N.E., and passes by the deserted Khond hamlet of Rájan. The pillar is solid, and contains two marks, one at the upper surface and the other engraved on the rock *in situ*.

[The Astronomical Station is on a hill over 3,000 feet high (the highest in the vicinity) known locally as Khundahana. The surrounding country is broken by lower hills of various heights, their mass does not seem to predominate greatly in any particular direction. The mass of the hill itself lies mainly to the N.E. of the station, and for this reason a deflection

of 2" to the N.E. might be expected. The best way to the station is from Balugaon railway station *viâ* Banpur Pertap and Ankula. After Ankula coolie transport is necessary and a small camping ground can be found  $1\frac{1}{2}$  miles beyond the forest guard hut at Rájan. The Latitude was observed at the Trigonometrical Station.—E.A.T.]

Geodetic Latitude of the Astronomical Station =  $19^{\circ} 51' 12'' \cdot 90$

179. Kidarkanta Hill Station is a secondary station of the N.W. Himalaya Series (*vide* Synoptical volume VII). Its position was re-determined in 1903 by special triangulation (*vide* Appendix No. 2 of this volume). It is situated on the highest point of Kidarkanta hill on the watershed between the Tons and Jumna valleys in the lands of the village Durgaon (Tehri-Garhwál), and is about  $\frac{1}{4}$  mile E. of the higher road from Onot and Bahshul to Shauro. It is about  $3\frac{1}{4}$  miles N.N.E. of Our,  $3\frac{3}{4}$  miles E. of Lodráo and  $3\frac{1}{2}$  miles S. of Shauro village. In 1903 the Astronomical Party marked the station by a circle and dot cut on the upper surface of a stone embedded centrally in a circular masonry pillar 3 feet in diameter and 2 feet high. Vertically below the upper mark, a similar mark was embedded below the pillar. The pillar was isolated in the usual manner from the surrounding platform, which was built up to the level of the upper surface of the pillar. The station is most easily approached from the north, the best route being *viâ* Chakráta, Mandali, Thadiar, Sendra Forest Bungalow, Naintwar Forest Bungalow (by Gainchra village) and Kidarkanta.

[The Astronomical Station is 38 feet south and 32 feet east of the Trigonometrical Station. The station seems well placed as regards the mass of the hill itself, and no local disturbance of the plumb-line of any importance need be expected. There is a small preponderance of mass to the south.—H.M.C.]

Geodetic Latitude of the Trigonometrical Station =  $31^{\circ} 1' 22'' \cdot 09$

Reduction to Astronomical Station =  $- 0 \cdot 38$

Geodetic Latitude of the Astronomical Station =  $31 \ 1 \ 21 \cdot 71$

180. Kistama Hill Station (No. XXXI of the Madras Meridional and Coast Series, volume XIII of the *Account of the Operations &c.*) is situated in the lands of the village of Prabhagiripatnam, taluk Atmakur, district Nellore. It is on the top of Kistama hill. The directions and distances of the circumjacent villages are:—Prabhagiripatnam W. by N., mile  $\frac{1}{2}$ ; Navuru W.N.W., miles  $5\frac{1}{2}$ ; Bhattulapalle N.W. by N., miles  $5\frac{1}{2}$ ; and Tatiparti N. by E., miles  $4\frac{1}{2}$ . The station consists of a platform of stones and earth enclosing a solid, circular and isolated pillar of masonry,  $3\frac{1}{3}$  feet in diameter in which are two marks, one engraved on the rock *in situ* and the other 2·6 feet above it and level with the upper surface of the pillar.

[The Astronomical Station coincides with the Trigonometrical Station and is on the top of the eastern of two twin hills each about 350 feet above the surrounding country. The station is well placed over the centre of the hill mass. There are isolated peaks both to north and south, varying from  $1\frac{1}{2}$  miles to 30 miles distant, but no deviation in the meridian is to be expected on account of them, as the attraction in each direction should be nearly equal. A new road from Podalakur to Sangam is under construction and this runs within two miles of Kistama hill, for the last two miles there is no road.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $14^{\circ} 27' 14'' \cdot 56$

181. Kurseong Hill Station (a secondary station of the North-East Longitudinal Series) is situated on the Kurseong spur. The part of the spur on which it is situated is extremely narrow. The road from the Kurseong Railway Station going in a south-westerly direction towards Ambhuttia and Pankhabari Tea Estates passes alongside and to the north of the station. The station is about  $1\frac{1}{4}$  miles distant from the Railway Station of Kurseong. The bifurcation of roads, the one leading to Ambhuttia in a westerly direction, the other to Pankhabari in a southerly direction takes place about 350 yards S.W. of the station. The Kurseong Church and Cemetery are about 500 yards N.E. of the station. The pillar is cylindrical 3 feet in diameter and 2 feet high, the upper surface being flush with the ground. There are two mark-stones, one vertically over the other at an interval of about 2 feet. The mark-stones have engraved on them a dot and concentric circles. The upper mark-stone is on the surface of the platform.

[The Latitude pillar is 485 feet due west of the Trigonometrical Station and is 113 feet lower in altitude.—H.M.C.]

Geodetic Latitude of the Astronomical Station =  $26^{\circ} 52' 5'' \cdot 56$

182. Ládimsir Tower Station (No. XVII of the Sutlej Series, volume IV of the *Account of the Operations &c.*) stands on the summit of one of a group of sand-hills in the desert east of Baháwalpur. It is in the Baháwalpur territory. The village from which the station takes its name is distant about  $\frac{2}{3}$  of a mile to the N.E. The pillar is perforated and has a mark-stone at the level of the ground floor.

[Perfectly flat sandy desert, plumb-line unaffected by hills, The Latitude pillar was 600 feet due east of the Trigonometrical Station.—s.g.b.]

Geodetic Latitude of the Astronomical Station =  $29^{\circ} 21' 41'' \cdot 58$

183. Lambatach Hill Station is a secondary station of the N.W. Himalaya Series (*vide* Synoptical volume VII). Its position was re-determined in 1903, (*vide* Appendix No. 2 of this volume). It is situated on the highest point of Lambatach hill, which lies N.E. of the junction of the Pabar and Tons rivers, in the lands of the village Manjni (Tehri-Garhwál), about  $1\frac{3}{4}$  miles N.W. of Deota Forest Bungalow, 1 mile N.E. of Majon and Lambatach Forest Bungalow. In 1903 a circle and dot were cut in a stone embedded in the upper surface of a masonry pillar 3 feet in diameter and one foot high. This dot was placed vertically over the old mark defining Lambatach or Lambáthush of the secondary triangulation. The pillar is isolated in the usual manner from the surrounding platform. The easiest approach is *viâ* Thadiar and Deota Forest Bungalows.

[The Astronomical Station is 82 feet  $1\frac{1}{2}$  inches north and 1 foot  $8\frac{1}{2}$  inches east of the Trigonometrical Station. There may be a slight local deflection of the plumb-line southwards, probably less than 1" in amount.—H.M.C.]

Geodetic Latitude of the Trigonometrical Station =  $31^{\circ} 1' 7'' \cdot 65$   
Reduction to Astronomical Station = +  $0 \cdot 81$

Geodetic Latitude of the Astronomical Station =  $31 \quad 1 \quad 8 \cdot 46$

184. Lingmára (or Báláji-ka-pahár) Hill Station (No. XVI of the Jabalpur Meridional Series, volume VI of the *Account of the Operations &c.*) is in the tahsil and thána of Rámpaili, and the district of Bálághát, formerly called Boorha, of the Central Provinces, the head quarters of the district being 10 miles to the north-east. The station is situated on the southern edge, and not on the highest part, of a long range of hills averaging 700 feet in height, and running east and west. To the immediate south of the range and  $\frac{1}{2}$  a mile distant are 5 conical hills 500 feet high.

[To avoid essentially local attraction, which promised to be considerable at the Trigonometrical Station, the Astronomical Station was built 1812 yards due east of the former, a site that was also east of the centre of gravity of the Lingmára range. 500 yards from the Astronomical Station in a N.N.E. direction is a small hillock 70 feet high: a heavy range of mountains looms along the northern horizon, 20 miles away, but the southern view is one unbroken plain. The Astronomical Station stands near the centre of a small plateau about 30 feet above the general level of the ground to the north and south. A northerly attraction should be expected here; the mountains to the N.N.W. and N.N.E. are shewn by the map to be more considerable than they appear to the eye; there is nothing on the southern side to counteract them, and the whole tendency of the ground level from 20 miles north of the station to 20 miles south of it is to slope downwards at 20 feet per mile.—s.g.b.]

Geodetic Latitude of the Astronomical Station =  $21^{\circ} 43' 3'' \cdot 07$

185. Lohágara Tower Station (No. XLII of the Calcutta Meridional Series, volume VIII of the *Account of the Operations &c.*) stands about a mile E. of a small stream called Nahara stream; and 7 miles S.W. of the large village of Dakkhin Batina on the high road from Dinajpur to Titalia, thána Thakurgaon, pargana Shálbári, district Dinajpur. The azimuths and perambulated distances of the circumjacent villages are:—Lakhipur  $215^{\circ} 56'$ , mile 0·73; Matrapur  $278^{\circ} 26'$ , miles 1·30; Raipur  $344^{\circ} 40'$ , mile 0·72; and Phakdampur  $82^{\circ} 20'$ , mile 0·11.

[The Latitude pillar is 42 feet east of the Trigonometrical Station and 2 feet south of the same. Some 8 feet of the Trigonometrical masonry pillar remain in good preservation—covered by a mound of earth. No "half way" mark was to be found and as it was thought inexpedient to open up more of the masonry pillar to get to the lower mark, the Latitude was referred to the centre of the square masonry pillar. It is very improbable that an error of as much as  $\pm 0'' \cdot 005$  has been thus introduced into the value for the reduction to the Trigonometrical Station.—H.M.C.]

Geodetic Latitude of the Trigonometrical Station =  $26^{\circ} 2' 12'' \cdot 04$   
Reduction to Astronomical Station = —  $0 \cdot 02$

Geodetic Latitude of the Astronomical Station =  $26 \quad 2 \quad 12 \cdot 02$

186. Losalli Station (No. I of the Karachi Longitudinal Series, volume III of the *Account of the Operations &c.*) is situated in the Sironj district of the Tonk territory,  $1\frac{1}{2}$  miles W. of Pagrani, and the same distance S.E. of Bara Losalli, on a gentle undulation of the high table-land which rises immediately to the west of the Sironj valley. Some of the circumjacent villages with their directions and distances are as follows:—Manakheri N., 2·33 miles; Alinagar W., 0·85 mile; and Bogra S.E., 3·39 miles. The pillar is solid,  $14\frac{1}{2}$  feet high, and has the usual mark-stones at top and bottom, besides two intermediate ones at 5 and 10 feet respectively above the lower mark.

• [The Latitude pillar was to the west of the Trigonometrical Station and 60 feet from it. Its centre is practically in the prime vertical. Losalli Station is situated 1,749 feet above mean sea-level and in the middle of the Kaliánpur plateau, in perfectly flat ground, which is slightly lower than the undulating country to the west.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $24^{\circ} 6' 19'' \cdot 17$

187. Lúnki Hill Station (No. LXXI of the Karachi Longitudinal Series, volume III of the *Account of the Operations &c.*) is situated on a sand-hill in that portion of the Thar, or Little-desert, appertaining to Bhúj. The village of Dadia is S.E. at about 2 miles, and that of Janji-ká-kúa N.W. at about 1·7 miles. The station consists of a solid pillar 3 feet high, having three mark-stones, one at top, another at bottom and a third 2 feet above the latter.

[The Astronomical Station is over the Trigonometrical Station of the same name, the centre of the instrument being 1 foot south of the Trigonometrical mark. The Trigonometrical Station is on the highest ridge of the locality and was found in good condition.—H.M.C.]

Geodetic Latitude of the Trigonometrical Station =  $24^{\circ} 58' 23'' \cdot 16$   
 Reduction to Astronomical Station =  $- 0 \cdot 01$

Geodetic Latitude of the Astronomical Station =  $24 \ 58 \ 23 \cdot 15$

188. Madhupur (Modupur) Tower Station (No. XIV of the Calcutta Meridional Series, volume VIII of the *Account of the Operations &c.*) is situated immediately on the right bank of the Jwalangi river and about a mile below its junction with the Bhairali; thána Nauda, pargana Kulberia, district Murshidabad. The azimuths and perambulated distances of the circumjacent villages are:—Madhupur (Indigo factory)  $79^{\circ} 35'$ , mile 0·48; Madhupur  $120^{\circ} 47'$ , miles 1·41; Dengapára  $179^{\circ} 59'$ , miles 1·31; Piárpur  $304^{\circ} 29'$ , miles 1·99; and Belnagar  $233^{\circ} 47'$ , mile 0·68. The station consists of a square tower of masonry 33·25 feet in height which has a mark-stone at bottom.

[The Latitude pillar is in the prime vertical of the Trigonometrical Station and 492·9 feet east of the same. There is nothing visible to which local deflection of the plumb-line could be attributed. The country seems of uniform character for miles all around,—flat low lying, alluvial tracts, wooded or under cultivation. The Trigonometrical Station is in excellent preservation.—H.M.C.]

Geodetic Latitude of the Astronomical Station =  $23^{\circ} 56' 38'' \cdot 97$

189. Madras Longitude Station (*vide* volume IX of the *Account of the Operations &c.*) was 65 feet due north from the axis of the Meridian Circle of the Madras observatory, which latter point was fixed by triangulation and called Madras Observatory No. 2 s. in Synoptical Volume XXVII of the Madras Longitudinal Series.

[The zenith telescope was set up on a small circular granite pillar originally erected by some officers of the U. S. Navy who were engaged on Electro-Telegraphic Longitude operations; it was on the same meridian as the Longitude Station of the Survey of India, and 41 feet  $7\frac{1}{2}$  inches north of it. The zenith sector pillar was 30 feet  $7\frac{1}{2}$  inches due east of the zenith telescope pillar.—S.G.B.]

Geodetic Latitude of the Longitude Station =  $13^{\circ} 4' 3'' \cdot 75$   
 Reduction to Latitude Station =  $+ 0 \cdot 42$

Geodetic Latitude of the Latitude Station =  $13 \ 4 \ 4 \cdot 17$

190. Mahadeo Pokra Hill Station is situated in Central Nepal: the station is marked with a pile of stones 6 feet in diameter and 6 feet high. The position of the station was determined from observations to known peaks.

Captain Wood's "*Report on the Identification and Nomenclature of the Himalayan Peaks as seen from Katmandu, Nepal*" published in 1904, gives the geodetic co-ordinates of Mahadeo Pokra as follows:—

Latitude  $27^{\circ} 41' 31'' \cdot 5$

Longitude  $85^{\circ} 33' 47'' \cdot 1$ .

191. Majhár Hill Station (No. XIV of the Budhon Meridional Series, volume VII of the *Account of the Operations &c.*) is situated on the same elevated plateau as Gujara fort from which it is distant about  $1\frac{1}{2}$  miles due north: in the Gwalior State. The distances and directions of neighbouring places are: Jamrúha fort 2 miles, E.N.E.; and Naugamo village 3·1 miles, E.S.E. The station consists of a solid pillar, having a mark-stone at its upper surface.

[The Latitude pillar is 41 feet east of the site of the Trigonometrical Station. The original low tower and platform of which the Trigonometrical Station consisted, had fallen and about the year 1892 the platform was rebuilt by the local official to a height of about six feet. Some seven years later a small stone tower was built on the platform, in height some eight feet above the platform. The original top mark-stone which had fallen, is now, in 1902, to be seen built into the side of the platform. The lower mark seems to have been destroyed as none was found. The Latitude pillar

cannot be more than 4 feet out of position however. The local visible masses are capable of producing a slight deflection of not more than  $0''\cdot5$  southwards.—H.M.C.]

Geodetic Latitude of the Astronomical Station =  $26^{\circ} 6' 17''\cdot00$

192. Mal Hill Station (No. LI of the East Coast Series, volume VI of the *Account of the Operations &c.*) is situated in the lands of the village of Birimi on a low hill stretching about 1·5 miles, N.E. and S.W.; zamíndári Mandisa, district Ganjam. The hill originally belonged to Ankápilli, but that village having been abandoned it was attached to Birimi. The village of Birimi lies E.N.E., distant about 1 mile and the sea-coast is about 1·5 miles E. The station consists of a solid pillar, having two marks, the upper 1·50 feet above the lower which is engraved on the rock *in situ*.

[The Astronomical Station is on a hill nearly 500 feet high, or 350 feet above the surrounding plains. The country is interspersed with low hills. The local attraction of those in the immediate vicinity, including that on which the station stands, would probably be a little N. by E, but there are heavy masses of hills, rising to nearly 5,000 feet about 16 miles distant to N.W. A local attraction towards the N.W. should be expected accordingly. This is however neglecting any effect which may be due to the fact that the sea-coast is within 2 miles in a S.E. direction from the station, the general direction of coast line being N.E. to S.W. The Astronomical Station coincides with the Trigonometrical Station.—E.A.T.]

Geodetic Latitude of the Astronomical Station =  $18^{\circ} 47' 16''\cdot97$

193. Mándvi Hill Station (No. XXXI of the Bombay Longitudinal Series, volume XII of the *Account of the Operations &c.*) is situated in the lands of the village of Tikona, táluks Pová and Mával, Bhór State. It is on a ridge of the Western Gháts and occupies the peak locally known as Mándvi: it is  $1\frac{1}{2}$  miles W. of the village of Vaula whence there is a very decent path to the station, and  $1\frac{3}{4}$  miles E. of Tikona hill fort which is connected with it by a remarkable ridge about a mile in length along which there is a foot-path. The station is at the N. end of the summit which rises precipitously from all sides to a height of about 500 feet above the level of the high ridges of the table-land. The hill is composed generally of hard vesicular basalt; the lower part is of amygdaloid. The directions and distances of the circumjacent villages are:—Malaundi N.W. by N., mile 1; Kásig S.W. by W., miles  $1\frac{1}{2}$ ; Kolván S., miles  $3\frac{1}{2}$ ; and Audhali S.E. by E., miles  $1\frac{3}{4}$ . The station consists of a solid pillar of masonry having two marks.

[The Astronomical Station is coincident with the Trigonometrical Station. This is situated at the summit of a conical peak of the Western Gháts. Its height is 4,110 feet above sea-level, and about 2,200 feet above the surrounding country. There are mountains on every side and it is impossible to foretell what their effect may be on the plumb-line; so far as the more immediate surroundings are concerned, an attraction to the south seems probable, as to the north the fall is very abrupt and there is a valley on this side about 4 miles wide, while to the south the hill extends, though at a low altitude, for a long way.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $18^{\circ} 37' 51''\cdot11$

194. Mooltan Longitude Station (*vide* volume XV of the *Account of the Operations &c.*) is about 53 feet north and 102 feet east of Mooltan Telegraph Office station, which is situated at the N.W. angle of the *paka* roof of the Government Telegraph Office. A circle and dot engraved on a stone let into the roof marks the Telegraph Office station. It is 2·83 feet from an arrow on the western parapet, 8·08 feet from the S.W. corner of the westerly of the two northern chimneys and 9·96 feet from the N.W. corner of the single central chimney.

[Suleimán mountain peaks just visible to N.W. on very clear days: otherwise the whole country is flat. The Latitude Station was coincident with the Longitude Station.—S.G.B.]

Geodetic Latitude of the Latitude Station =  $30^{\circ} 10' 58''\cdot70$

195. Moulmein Longitude Station (*vide* volume X of the *Account of the Operations &c.*) is on the meridian of the Mess House station, 10·0 feet south of it. In 1884 a marble slab 15 inches square with a circle and letters G. T. S. painted thereon was placed between the transit pillars.

[The Latitude was observed from the Moulmein Longitude Station, the zenith telescope being placed on the westernmost of the two Transit pillars. These pillars were found in sound condition. The adjacent building described in Volume X is no longer the Mess House of Moulmein Volunteer Rifles. It is a private dwelling house. It is situated on the high ground of "Battery Point". In January 1905 there was no marble slab between the two transit pillars.—H.M.C.]

Geodetic Latitude of the Latitude Station =  $16^{\circ} 29' 54''\cdot62$

*Note.*—It will be found that the Geodetic Latitude of the Longitude Station as given in Volume X is  $1''\cdot87$  in excess of the value adopted here. The Series of Triangulation following the Burma Coast emanates from the side Gojalia, XLIX—Tulamura L of the Eastern Frontier Series. The values of the length and azimuth of this side were adjusted in the simultaneous reduction of the North-East Quadrilateral and this adjustment has necessitated a recalculation of the triangulation in Burma.

196. Nagarkhána Hill Station (No. LXXI of the Burma Coast Series, Section  $11^{\circ}23'$ ) is situated on the westernmost range in the Chittagong district known by the Muggs as the Hinglimoin Range, and extending from the Fenny river on the north to the Karnaphuli on the south, the range runs in a direction N.W. and S.E. and is distant from the latter river about 4 miles. It is on eastern edge of the range, overhanging the plains about  $\frac{1}{2}$  mile distant from the village of Naseerabad at W. A large tank, the Sultan Bajubasta *dargah* is situated N.N.E. about  $\frac{1}{2}$  mile, and the Judge's Kachahri in the civil station of Chittagong is distant 2·896 miles at an azimuth of  $318^{\circ}58'39''\cdot51$ . The station is in pargana Naseerabad, in thána and zillah Chittagong, and is marked by a masonry pillar 3 feet high and  $3\frac{1}{2}$  feet in diameter at top. The pillar contains 3 mark-stones, one at the top and the others 2 feet apart, the lowest being a foot below the surface of the hill.

[The Latitude Station is 23 feet 2 inches east of the Trigonometrical Station.—P.M.C.]

Geodetic Latitude of the Astronomical Station =  $22^{\circ}22'56''\cdot38$

197. Náharmau Hill Station (No. VI of the Calcutta Longitudinal Series, volume VI of the *Account of the Operations &c.*) is situated within a ruined fort on a hill about half a mile S.E. of the village of that name; thána Gaurjhamar, tahsil Rehli, district Saugor. On the hill top, adjacent to the Trigonometrical Station, is a reservoir of water, known as Nilkanth Maháraj's tank, which is resorted to by pilgrims immediately after the setting in of the rains. The station consists of a solid pillar 2 feet high, having two marks.

[The Latitude pillar is 2010 feet west of the Trigonometrical Station. The azimuth of pillar from Trigonometrical Station measured from north by west is  $89^{\circ}58'35''$ . The Náharmau hill lies slightly to N.E., while to N.N.W. and W. there are extensive low lying tracts. To S.E. and S. is broken hilly country. No large masses are involved and the existence of more than a very small local attraction to south is not to be expected.—P.M.C.]

Geodetic Latitude of the Trigonometrical Station =  $23^{\circ}30'18''\cdot14$   
Reduction to Astronomical Station = +  $0\cdot01$

Geodetic Latitude of the Astronomical Station =  $23\ 30\ 18\cdot15$

198. Niálamari Hill Station (No. II of the Madras Meridional and Coast Series, volume XIII of the *Account of the Operations &c.*) is situated in the lands of the village of Malkapuram, táluk Nalgönda, Nizam's territories. The azimuths and distances of the circumjacent villages are:—Niálamari  $251^{\circ}57'$ , miles 2·45; Chidalla  $27^{\circ}34'$ , miles 3·57; Malkapuram  $277^{\circ}1'$ , miles 1·97; and Súrayapet  $136^{\circ}25'$ , miles 9·8. The station consists of a platform enclosing a solid, circular and isolated pillar of masonry in which are two marks, one engraved on the rock *in situ* and the other 2 feet above it on a stone imbedded flush with the upper surface of the pillar.

[The Latitude pillar is built on the Trigonometrical Station. The hill on which the station stands is very steep, about 500 feet high and may be best described as one vast granite rock. There is a small hill due north about  $\frac{1}{2}$  mile off and two others N. by W. distant  $1\frac{1}{2}$  and 2 miles respectively and a considerable mass of hills N.N.W. distant 3 miles. There is a small hill due south distant 2 miles. All these hills are bare rocks. There is probably a small amount of northern local attraction.—J.E.]

Geodetic Latitude of the Astronomical Station =  $17^{\circ}1'33''\cdot63$

199. Nitali Hill Station (No. X of the Bombay Longitudinal Series, volume XII of the *Account of the Operations &c.*) is situated in the lands of the village of Nitali, district Naldurg, Nizam's territories. It lies on a hillock,  $1\frac{1}{2}$  miles N.N.W. of Nitali, and  $4\frac{1}{2}$  miles W. of Andúra village. The directions and distances of the circumjacent villages are:—Koand N.E., miles 2; Sumb W. by N., miles  $1\frac{3}{4}$ ; Javoti S.W. by W., miles  $2\frac{2}{3}$ ; and Bála E.N.E., miles  $4\frac{1}{4}$ . The station consists of a perforated pillar of masonry, having two marks, one at the bottom and the other at its upper surface.

[The Latitude Station is coincident with the Trigonometrical Station. It is situated on a low stony hillock in the midst of a large and slightly undulating plain. No hill of any importance is in sight so that there is no reason to suspect any deviation of the plumb-line.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $18^{\circ}17'7''\cdot16$

200. Ongole Hill Station (No. XVIII of the Madras Meridional and Coast Series, volume XIII of the *Account of the Operations &c.*) is situated in the lands of the town of Ongole, táluk Ongole, district Nellore. It is on a low hill about 200 feet in height, lying immediately W.S.W. of the táluk town of Ongole, and  $\frac{3}{4}$  of a mile W. of the road from Nellore to Ongole. The directions and distances of the circumjacent villages are:—Anavaripud E.S.E., mile 1; Perana Mitta N.W., miles  $3\frac{1}{4}$ ; Mámidipálém S.S.W., mile  $\frac{1}{2}$ ; and Guddalaguntapálém N.W., mile  $\frac{1}{2}$ . The station consists of a platform

enclosing a solid, circular and isolated pillar of masonry  $3\frac{1}{2}$  feet in diameter in which are two marks, one engraved on the rock *in situ* and the other 2 feet above it on a stone imbedded flush with the upper surface of the pillar.

[The Astronomical Station is coincident with the Trigonometrical Station and situated on the top of the northern of two small hills which lie to the south-west of the large town of Ongole and about half a mile from it. Owing to the presence of this hill to the south, the station is not a very good one, and it would have been preferable to select a station in the prime vertical, but no suitable spot could be found and so the old station was adhered to. The hill is about 300 feet higher than the surrounding country which is very flat. It is very rocky and is difficult to pitch tents on. Ongole is a large native town through which the main road to Hyderabad passes.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $15^{\circ} 29' 56''\cdot85$

201. Oria Hill Station is situated on a small plateau; it is 200 yards S.W. of the Rest-house, and 1 mile S.S.W. of Gúru Sikkar Hill Station (No. XLII of the Karachi Longitudinal Series, volume III of the *Account of the Operations &c.*)

[The position of Oria h.s. was fixed by secondary triangulation, specially executed for the purpose. The original intention of the observer was to observe from Gúru Sikkar, but a landslip had destroyed the path, and it was not possible without great expense to take the heavy Zenith Sector to the peak. It is intended in the future to observe with the Zenith Telescope at several stations situated on a section through Mount Abu: of these stations Gúru Sikkar and Oria will form two. The Latitude Station was originally misnamed Gúru Sikkar, but in view of its great distance from the Principal Station of that name, and of the prospect of latitude observations being taken in the near future at Gúru Sikkar itself, it has been considered advisable to rename it Oria.—S.G.B.]

Gúru Sikkar Hill Station is situated on the highest pinnacle of Mount Abu, in the territories of the Ráo of Sirohi, in Rajputana. The small rock temple of Gúru Sikkar, a resort of pilgrims from all parts of India, adjoins the station platform towards the S.W. The station consists of a solid pillar of masonry having a mark-stone at its upper surface and another engraved on the rock *in situ*.

Geodetic Latitude of the Astronomical Station at Oria =  $24^{\circ} 37' 50''\cdot96$

202. Parampúdi Hill Station (No. LX of the Madras Meridional and Coast Series, volume XIII of the *Account of the Operations &c.*) is situated in the lands of the village of Parampúdi, taluk Yérna-gúdēm, district Godáviri. It is on a low hill about 4 miles W. by N. of the large village of Ganapavaram, the same distance E. of Jelugumilli, and 5 miles N. of the large village of Taduvayi. The directions and distances of the circumjacent villages are:—Rámanapálēm W.S.W., miles  $2\frac{3}{4}$ ; Vírachēttigúdēm S.W. by W., miles  $1\frac{3}{4}$ ; Ganganagúdēm S.E. by S., miles  $2\frac{1}{4}$ ; Rantugúdēm E. by S., miles  $2\frac{1}{4}$ ; and Nar-napuram N.E. by N., miles  $1\frac{1}{2}$ . The station consists of a platform of stones and earth enclosing a solid, circular, and isolated pillar of masonry in which are two marks, one engraved on the rock *in situ* and the other  $2\frac{1}{2}$  feet above it on a stone imbedded flush with the upper surface of the pillar.

[The Astronomical Station is identical with the Trigonometrical Station. This is situated at the highest point of a small rising ground of insignificant height. There is nothing to lead to the anticipation of any deviation of the plumb-line.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $17^{\circ} 12' 38''\cdot28$

203. Patháídi Tower Station (No. XIX of the Biláspur Meridional Series, volume VI of the *Account of the Operations &c.*) is situated on rising ground 0·17 mile E.N.E. of the deserted village of Patháídi, pargana Ratanpur, district Biláspur of the Central Provinces. The azimuths and distances of the following villages are:—Keonthara  $170^{\circ} 10'$ , miles 1·70; and Kári  $207^{\circ} 10'$ , miles 1·88. The station consists of a perforated pillar of masonry 25·13 feet high, having a mark-stone in the ground floor and another 2 feet below.

[Patháídi is a tower station; the masonry core was found intact, but the outer mud masonry has long since collapsed into a shapeless mound which envelopes the tower for half its height. There was no cause to expect any local attraction. The Latitude pillar was erected 318·5 feet to the west of the Trigonometrical Station and was found to be 1·5 feet south of its proper position in the prime vertical.—E.A.T.]

Geodetic Latitude of the Trigonometrical Station =  $21^{\circ} 48' 45''\cdot97$   
Reduction to Astronomical Station =  $- 0\cdot01$

Geodetic Latitude of the Astronomical Station =  $21\ 48\ 45\cdot96$

204. Patna Tower Station (No. XV of the East Coast Series, volume VI of the *Account of the Operations &c.*) is situated on the left bank of the Subarnarekha river at the northern extremity of the village of Patna in pargana Jellasore, district Balasore. The Baptist Mission Chapel is 100 yards south-west of the station. The azimuths and perambulated distances of the circumjacent villages

are:—Súkdúkhia  $123^{\circ} 28'$ , mile 0.908; Bhelbaria  $172^{\circ} 24'$ , mile 0.432; Chakharia  $209^{\circ} 41'$ , mile 0.762; Bagawáli  $257^{\circ} 55'$ , mile 0.566 and Balampur  $357^{\circ} 7'$ , mile 0.464. The tower is solid, 36.50 feet high, and has a central pillar of masonry, isolated from the ground level upwards, in which the mark-stones have been placed.

[The station is by the road about  $1\frac{1}{4}$  miles from Jellasore Railway Station; 50 yards to the north of it flows the Subarnarekha river, flowing at this point roughly from E. to W. The kachcha portion of the tower is in ruins, but the paka core appears intact, and the upper mark-stone uninjured. The Latitude pillar is 40 feet 9-inches due west of the Trigonometrical Station. There are no hills in the vicinity to cause local attraction; the effect of the channel of the Subarnarekha, which is here some 400 yards broad with its bed 20 feet to 30 feet lower than the surrounding country, would probably be nearly balanced by the fact that the country is falling imperceptibly to the south. No local attraction should be anticipated accordingly. The sea is nearly 20 miles distant in a S.S.E. direction—E.A.T.]

Geodetic Latitude of the Astronomical Station =  $21^{\circ} 47' 20'' \cdot 83$

205. Phallut Hill Station (a secondary station of the North-East Longitudinal Series) is situated on the watershed boundary between British Sikkim and Nepal; Pillar No. 1 of the series of pillars defining the said boundary is about 30 feet to the north of the station. This boundary pillar is the tri-junction point of British Sikkim, Independent Sikkim and Nepal. The Traveller's Bungalow lies S.E. of the station at a distance of about 1150 feet measured horizontally. The frontier road terminates about 60 feet north of the station.

[The Trigonometrical mark had been destroyed and all traces of the pillar removed. The description given of the station says that it was "about 30 feet" south of Boundary Pillar No. 1 of the Sikkim-Nepal Boundary. The highest point on the hill is this distance south of the Boundary Pillar, and as the ridge here is very sharp and runs roughly S.E. to N.W., there is little doubt as to where the station originally was; on this spot was found the usual Bhutia cairn and prayer flags. The position of this reclaimed point cannot be more than 1 foot north or south of the original mark. The Astronomical Station is 97.8 feet south and 88.3 feet east of the assumed point. The azimuth and distance of Boundary Pillar No. 1 from the Astronomical Station are  $144^{\circ} 0'$  (from S. by W.) and 160.6 feet respectively.—H.M.C.]

Geodetic Latitude of the Trigonometrical Station =  $27^{\circ} 12' 41'' \cdot 83$   
Reduction to Astronomical Station =  $\quad \quad \quad - \quad 0 \cdot 97$

Geodetic Latitude of the Astronomical Station =  $27 \quad 12 \quad 40 \cdot 86$

206. Pirmulo Hill Station (No. V of the Bider Longitudinal Series, volume VI of the *Account of the Operations &c.*) is situated on a rock 10 feet high on a hill within the lands of the village of Wadapaili, pargana Tupren, Zilla Medak of the Nizam's territories. A road from Wadapaili village leads to the station. The bearings and estimated distances of the circumjacent villages are:—Wadapaili W.S.W., miles 1.3; Rámaram N. by W., miles 2; Ginpaili E.S.E., miles 2.3. The station consists of a solid pillar having two marks, the upper 1.13 feet above the lower, which was found deeply engraved on the rock *in situ* and adopted for the station.

[The Trigonometrical Station of this name being unsuitable for the observations, a new station was selected to the east. The azimuth of this station from the original one is  $270^{\circ} 32' 56''$  and the horizontal distance between the two 1460.5 feet. Hence the Astronomical Station is 13.99 feet south of the Trigonometrical Station. There is a small hill to the north, the highest point being about 350 yards distant and 150 feet above it. The mass of the hill is small but being so close may have some slight effect on the plumb-line.—G.P.L.C.]

Geodetic Latitude of the Trigonometrical Station =  $17^{\circ} 53' 2'' \cdot 95$   
•Reduction to Astronomical Station =  $\quad \quad \quad - \quad 0 \cdot 14$

Geodetic Latitude of the Astronomical Station =  $17 \quad 53 \quad 2 \cdot 81$

207. Prome Longitude Station (*vide* volume X of the *Account of the Operations &c.*) is 105.3 feet due east of Prome Club s., and about 120 feet south-east of the Prome Club and Reading Room.

[The Latitude Station is 71 feet 2 inches north and 2 feet east of the Longitude Station. The old Reading Room appears to have been moved to make way for the buildings of the Pumping Station. Prome Club s. is described as being 120 feet south-east of the Prome Reading Room. The present Club and Reading Room lies midway between the Longitude and Club Stations, which are no longer intervisible. The Longitude Station is marked by a marble slab in the surface of the concrete tennis court of the Club. The Club Station is in good condition.—H.M.C.]

Geodetic Latitude of the Longitude Station =  $18^{\circ} 49' 13'' \cdot 47$   
Reduction to Latitude Station =  $\quad \quad \quad + \quad 0 \cdot 71$

Geodetic Latitude of the Latitude Station =  $18 \quad 49 \quad 14 \cdot 18$

Note.—It will be found that the Geodetic Latitude of the Longitude Station as given in Volume X is  $1'' \cdot 65$  in excess

of the value adopted here. The Series of Triangulation following the Burma Coast emanates from the side Gojalia, XLIX—Tulamura, L of the Eastern Frontier Series. The values of the length and azimuth of this side were adjusted in the simultaneous reduction of the North-East Quadrilateral and this adjustment has necessitated a recalculation of the triangulation in Burma.

208. Quetta Telegraph Office Station is a station of the Quetta Secondary Series which emanates from the Great Indus Series. It is situated in the compound of the house occupied by the Deputy Superintendent of Telegraphs, Quetta Division, and lies between the house and an out-office east of the house. It is 58·33 feet from the S.E. corner of the house, and 66·5 feet from the south corner of the out-office. The station consists of a platform enclosing a circular, isolated pillar of masonry having a wooden peg in its centre with two lines cut on it.

[The Latitude Station is coincident with the Quetta Telegraph Office Station, which is 22·25 feet west and 8·08 feet north of the Quetta Longitude Station (*vide* volume XV of the *Account of the Operations &c.*)]

Geodetic Latitude of the Latitude Station =  $30^{\circ} 11' 57'' \cdot 37$

209. Rájpur Latitude Station is situated about the centre of the small level field immediately to the east of the ruined bungalow known as Seal's Kothi which stands just to the east of the upper end of the Rájpur Bazar. It consists of a circular masonry pillar 3 feet in diameter and 2 feet 6 inches in height, its upper surface level with the ground.

[The Latitude Station was connected by secondary triangulation with Kulhán s. and Rájpur h s., secondary stations of the North-East Longitudinal and Great Arc Meridional Series, Section  $24^{\circ}$ - $30^{\circ}$ , respectively. For the purposes of triangulation a point was selected 16 feet south and 9 inches west of the centre of the Latitude pillar.—G.P.L.C.]

Geodetic Latitude of the Trigonometrical Station =  $30^{\circ} 23' 56'' \cdot 67$

Reduction to the Latitude Station =  $+ 0 \cdot 16$

Geodetic Latitude of the Latitude Station =  $30 \ 23 \ 56 \cdot 83$

210. Rájuli (or Károba-ka-Dúngar) Hill Station (No. XXX of the Jabalpur Meridional Series, volume VI of the *Account of the Operations &c.*) is situated in the lands of the village of Balárpur, tahsil Múl, district Chánda. The station consists of a solid pillar of masonry 9 feet high, having at least two mark-stones, the distance between which is not known.

[The Astronomical Station was built over the mark-stone of the Trigonometrical Station. It is situated on the highest part of a small hill, 400 feet high. To the immediate north are two more similar hills but not so large, the three together forming one small range 2 miles in length. The horizon from west to south-west is broken by a small cluster of low hills, 7 or 8 miles distant: with the exception of these and a few detached hillocks 100 to 200 feet high scattered about to the north, the entire field of view is one unbroken plain, studded in every direction with tanks. The Astronomical Station is slightly north of the centre of gravity of the Rájuli Hill itself. The surrounding hillocks are so small and low, that their effect on the plumb-line must be inappreciable: the ground however has a very constant fall from north to south. This station should be a suitable one for Latitude observations, and the amount of local attraction is insignificant.—S.G.B.]

Geodetic Latitude of the Astronomical Station =  $20^{\circ} 12' 55'' \cdot 45$

211. Ramai Hill Station (No. XXXIII of the Biláspur Meridional Series, volume VI of the *Account of the Operations &c.*) is situated in the lands of the village of Ameti; zamíndári Fingeshwar, district Ráipur of the Central Provinces. It stands on a small detached flat hill, situated in the midst of a low densely wooded mass of hills, lying north and south, overlooking the plains to the west called the Ramai-Pát. The azimuths and estimated distances of the circumjacent villages are:—Sorid  $10^{\circ} 41'$ , miles 1·5; Nawápára  $310^{\circ} 56'$ , miles 1·75; and Ameti  $323^{\circ} 26'$ , miles 1·5. The station consists of a solid pillar of masonry having two marks, the upper 4·00 feet above the lower which is engraved on the rock *in situ*.

[Ramai Hill Station is on the southern end of a steep flat-topped hill rising to a height of about 450 feet above the surrounding plain; there is no visible cause for a marked local attraction in any particular direction. The Astronomical Station is identical with the Trigonometrical Station.—E.A.T.]

Geodetic Latitude of the Astronomical Station =  $20^{\circ} 56' 51'' \cdot 47$

212. Rámgrí Hill Station (No. XIV of the Bider Longitudinal Series, volume VI of the *Account of the Operations &c.*) is situated in the jágir of Fakírán Múl (son-in-law of the Nawáb Salár Jang) in the Hyderabad States, and has been built on the site of an old platform supposed to be Colonel Lambton's "Ramgeer". It is in the middle of a flat-topped conspicuous range with very precipitous approaches. From about half a mile to the east of the station the hill is extensively

fortified and the works are on a most stupendous scale. The village of Rámگیر lies about 5 miles E. The station consists of a solid pillar of masonry 8·25 feet high, having at least two marks, the distance between which is not known.

[The Latitude pillar is built on the Trigonometrical Station, situated on the plateau on which the ruins of the fort of Rámگیر stand. The particular part of the plateau on which the station is built runs N.W. and S.E. and there is apparently as much to the north as to the south. To the north there are no hills of any description; but to the south as far as the eye can reach, some 50 miles, there is a succession of hills and hillocks of all descriptions dotted about. There is probably some southern local attraction.—J.E.]

$$\text{Geodetic Latitude of the Astronomical Station} = 18^{\circ} 35' 26'' \cdot 12$$

213. Ranjítgarh Tower Station (No. XCV of the Gurbagarh Meridional Series, volume IV of the *Account of the Operations &c.*) is built in the old fort of that name, close to the road from Siálkot to Chaprá and Jummo, and distant about 7 miles from station of Siálkot; zilla, pargana and thána of Siálkot. The pillar is perforated and 20·5 feet high. It has a mark-stone at the ground floor.

[The Astronomical Station is 299½ feet west and 1·48 feet north of the Trigonometrical Station. The latter is situated on a mound, which forms part of the old fort of Ranjítgarh, ½th of a mile E.N.E. of the village of Khampur. This village is 7 miles from Siálkot on the Jummo Chaprá road. A large northerly deflection of the plumb-line, perhaps 10", might be expected due to the Himalayan masses some 40 miles to the N.—H.M.C.]

$$\begin{array}{rcl} \text{Geodetic Latitude of the Trigonometrical Station} & = & 32^{\circ} 35' 12'' \cdot 10 \\ \text{Reduction to Astronomical Station} & = & \quad + \quad 0 \cdot 01 \end{array}$$

$$\text{Geodetic Latitude of the Astronomical Station} = 32 \quad 35 \quad 12 \cdot 11$$

214. Ráwal Hill Station (No. LIX of the East Coast Series, volume VI of the *Account of the Operations &c.*) is situated on a low hill about 1 mile S.W. of the large village of Gángara in thána Pálkonda, taluk Parvatipur, district Vizagapatam. The nearest villages are Sítádípuram at the northern base of the hill and Ráwálsa at the southern base. The station consists of a solid pillar having two marks, the upper 1·75 feet above the lower which is engraved on the rock *in situ*.

[The Astronomical Station is on a group of hills running E. and W. It is at a height of 600 feet above the surrounding plain (this was measured with 6" theodolite from a 10 chain base). The local attractions of the range of hills on which the pillar stands would appear to cancel, but this is a difficult thing to estimate. There are hills all round except to the E. and S.E. The masses of the Eastern Gháts lying 30 miles W. and 40 miles N. should exert a W.N.W. attraction, but there is a considerable mass of hills 15 miles N.E., and a few small hills to the S., 8 miles distant. On the whole a probable attraction of 6" N. should be considered. The Astronomical Station coincides with the Trigonometrical Station.—E.A.T.]

$$\text{Geodetic Latitude of the Astronomical Station} = 18^{\circ} 32' 9'' \cdot 22$$

215. Rojhra Hill Station (No. LXXV of the Karachi Longitudinal Series, volume III of the *Account of the Operations &c.*) was situated on a sand-hill in that part of the Thar, or Little-desert, appertaining to Bhúj. The village of Paráára is distant about 3½ miles to the N.N.W.

[The Latitude pillar is 28 feet due east of the remains of the Trigonometrical Station of the same name. The latter had disappeared entirely in 1900 and it was only by digging extensively that the remains of the foundations were found 4 feet below the surface. The centre of these foundations was adopted as the Trigonometrical Station.—H.M.C.]

$$\text{Geodetic Latitude of the Astronomical Station} = 24^{\circ} 57' 26'' \cdot 28$$

216. Salimpūr Tower Station (No. XXVI of the Budhon Meridional Series, volume VII of the *Account of the Operations &c.*) is situated on the crest of a mound (about 20 feet in height) distant 600 yards west of the small village of Salimpur: thána and tahsil Kásganj, pargana Bilráam, district Etah. The distances and directions of the surrounding villages are:—Badampur 0·9 mile, E.S.E.; Naráinpur 0·5 mile, S.; Kutubpur 1·2 miles, N.W.; and Dharampur 1·3 miles, N.E. by N. The station consists of a tower of sun-dried bricks and mud cement, 48 feet high and 13 feet square at top, having a central hollow core of burnt bricks; it has a mark-stone at 1 foot below the ground floor.

[The Latitude pillar was situated 1222 feet west of the Trigonometrical Station. The azimuth of the latter from the former was 270° 0' 20", so that the latitudes of the two points may be considered identical.—G.P.L.C.]

$$\text{Geodetic Latitude of the Astronomical Station} = 27^{\circ} 46' 36'' \cdot 46$$

217. Samdari Hill Station (No. VII of the Jodhpore Meridional Series, volume IVA of the *Account of the Operations &c.*) is situated on a small isolated, irregularly shaped hill locally named Mátalalasi, on the north bank of the river Lúni and close to the large village of Samdari, in taluk Siwána of the Jodhpur territories. The azimuths and distances of the circumjacent villages are:—Devalibari

66°, miles 1·7; Mokrundi 180°, miles 2·25; Deopura 243°, miles 2·1; and Kamáwas 335°, miles 2·6. The pillar, which is surrounded by a platform, is solid and contains three marks, one in the foundation, 2 feet below the ground, another flush with the hill top and the third on the surface of the pillar; the difference of heights between the upper and lower marks is 3·13 feet.

[The Astronomical Station is built on the prime vertical of the Trigonometrical Station, and about 600 yards west of the latter. The southern horizon is broken by a rocky range, but this is not sufficiently large to affect the plumb-line at Samdari sensibly. The nearest range is south-west rather than south. Due south is a hill some 20 miles distant, and to the S.E. are a few scattered hills. The northern horizon is free from hills. There is thus no apparent cause for any appreciable deflection of the plumb-line.—s.g.b.]

Geodetic Latitude of the Astronomical Station = 25° 48' 59"·55

218. Sánjib Hill Station (No. XLI of the Bider Longitudinal Series, volume VI of the *Account of the Operations &c.*) is situated in the estate of the Rája of Uratla, táluk Golgonda, district Vizagapatam. It is on the summit of a high and conspicuous hill so named, the most elevated of the group or range running parallel with the coast, of which it forms a part. The sea is about 10 miles from the station. The large village of Uratla, the residence of the Rája, lies about 3 miles N. and Gotiára, near which the ascent commences, is 2 miles E.N.E. The station consists of a solid pillar, having two marks, the upper 1·50 feet above the lower.

[The Astronomical Station is identical with the Trigonometrical Station. This is situated at the top of a lofty hill 2000 feet from base to summit. This hill is one of the highest points of the range which runs nearly N.E. and S.W. parallel to the coast. As there are large masses of hills on all sides except the west it is impossible to say what the resultant effect on the plumb-line is likely to be.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station = 17° 31' 18"·68

219. Sankráo Tower Station (No. XXVIII of the Budhon Meridional Series, volume VII of the *Account of the Operations &c.*) is situated on the site of an old fort on a high spur of the bank which bounds the southern edge of the *Khúdar* or low lands of the Ganges, and stands close to the west side of the village of Sankráo which is less than half a mile from the south bank of the old bed of that river; tahsil Atrauli, pargana Gangíri, district Aligarh. The distances and directions of the surrounding villages are:—Rustamnala 1·1 miles, W. by N.; Mohkampur 1·2 miles, S.S.E.; and Sikri 1·1 miles, E. by S. The station consists of a tower of burnt bricks and mud cement, 37·3 feet high and 14 feet in diameter at top, having a central hollow core of masonry; it has a mark-stone at 1 foot below the ground floor.

[The Latitude pillar was situated 1245 feet west of the Trigonometrical Station. The azimuth of the latter from the former was 270° 2' 15", so that the Latitude pillar was 0·82 foot north of the prime vertical of the Trigonometrical Station.—G.P.L.C.]

Geodetic Latitude of the Trigonometrical Station = 28° 2' 28"·99

Reduction to Astronomical Station = + 0·01

Geodetic Latitude of the Astronomical Station = 28 2 29·00

220. Sarey Khan Latitude Station is situated  $\frac{3}{4}$  mile S.W. of Sarandi Pat Hill Station (No. XI of the Jabalpur Meridional Series, volume VI of the *Account of the Operations &c.*) and near the village of Sarey Khan, thána Gour-Jhola, tahsil and district Seoni. The village of Sarandi Pat lies about 1½ miles N.N.E. and that of Chilki about 1 mile north. The station consists of a brick pillar, having two marks. Its position was fixed by secondary triangulation specially executed for the purpose.

[This Astronomical Station was formerly called Sarandi Pat, but as it is situated some distance from the Trigonometrical Station of that name it has been considered advisable to rename it Sarey Khan. The Astronomical Station is identical with the Trigonometrical Station of the special secondary triangulation.—s.g.b.]

Geodetic Latitude of the Astronomical Station = 22° 12' 55"·61

221. Sarkára Tower Station (No. XLV of the Budhon Meridional Series, volume VII of the *Account of the Operations &c.*) is situated close to the high road from Hardwár to Moradabad, and distant about 0·6 mile S.S.E. of the village of Sarkára, tahsil Dhámpur, pargana Sherkot, district Bijnor. The distances and directions of the surrounding villages are:—Rajmul 0·3 mile, S.S.E.; Nasírpur Bhunwari 1·3 miles, W.S.W.; and Salámpur Sarai 0·8 mile, S. by W. The station consists of a tower of unburnt bricks and mud cement, 14 feet in diameter at top, enclosing a central solid pillar of masonry 16·3 feet high; it has a mark-stone at summit.

[The Latitude pillar was situated 1702 feet east of the Trigonometrical Station on an azimuth of 270° 1' 33", it is therefore 0·77 foot south of the latter.—G.P.L.C.]

Geodetic Latitude of the Trigonometrical Station	=	29° 15' 46"·92
Reduction to Astronomical Station	=	— 0·01
Geodetic Latitude of the Astronomical Station	=	29 15 46·91

222. Saugor Hill Station (No. V of the Calcutta Longitudinal Series, volume VI of the *Account of the Operations &c.*) is situated on the Bhunria hill about half a mile due east of Saugor jail and immediately above the old mint. The station consists of a solid pillar 2 feet high, having two marks.

[The Latitude pillar is 39·5 feet due east of the Trigonometrical Station. Immediately to the north and west extends the hollow in which Saugor lies, some 600 feet below the general level of the tops of the surrounding hills. To the south and east runs the ridge which contains the flat-topped hill. This ridge extends for about 1 mile eastwards before the mass merges gradually in the plain, and for some 2½ miles southwards. The country in the immediate neighbourhood would lead one to expect a small southerly deflection of the plumb-line not exceeding 0"·5.—H.M.C.]

Geodetic Latitude of the Astronomical Station = 23° 49' 48"·07

223. Senehal Hill Station (a secondary station of the North-East Longitudinal Series) is situated about 7 miles south of Darjeeling, and about ¾ of a mile S.E. of Majling-jong (Tiger Hill), west of and below which is the old cantonment of Senehal. The approach to the station is from Jor-Bungalow, whence a road has been cut to Tiger Hill, and from the latter a pathway is followed to the station. The station is identical with Sir A. S. Waugh's point pertaining to the North-East Longitudinal Series. It consists of a paka pillar 3 feet in diameter, surrounded by a platform of stones 4 feet high.

[The Latitude observations were taken from the Trigonometrical Station. The station is situated well over the centre of the hill; ¾ of a mile to the north is Tiger Hill, the mass of which is balanced to a great extent by other masses to the south. Beyond and north of Tiger Hill the ground falls rapidly to the Rangit valley. This deficiency of mass is balanced by the fall to the plains on the south of the station. Considering only the masses within 10 miles radius of the station, there should be only a very small deflection of the plumb-line, perhaps as much as 1" and that to the south. The deflection in the prime vertical should be small and to the east.—H.M.C.]

Geodetic Latitude of the Astronomical Station = 26° 59' 8"·25

224. Siliguri Station (a secondary station of the North-East Longitudinal Series) is situated to the west of the Caragola-Darjeeling road and at the angle where it branches off to Pankhabari.

[The Astronomical Station consists of an isolated circular masonry pillar 3 feet in diameter and whose top is flush with the ground surface. It is 147 feet due east of Siliguri Trigonometrical Station. The Trigonometrical pillar was not found in very good condition and was therefore carefully rebuilt.—H.M.C.]

Geodetic Latitude of the Astronomical Station = 26° 41' 40"·37

225. Singáwáram Hill Station (No. XXIII of the Bider Longitudinal Series, volume VI of the *Account of the Operations &c.*) is on an isolated hill about 1 mile N.E. of the village of Gattúgúram, within the lands of which it is situated, táluk Bhadráhalam, district Upper Godávari of the Central Provinces. A road to the station was made from the village of Gattúgúram. The directions and distances of the circumjacent villages are:—Bhándargúram W., miles 1·5; Singáwáram N., miles 2; and Bhadráhalam (city) S.W. by S., miles 6·9. The station consists of a solid pillar, having two marks, the upper 3·88 feet above the lower which is engraved on a stone built into the foundation.

[The Astronomical Station is identical with the Trigonometrical Station. This is situated on an isolated hill of considerable height, about 500 feet. The station is considerably to the north of the centre of the hill, which is likely therefore to cause some deviation to the south in the plumb-line. In other respects there is no cause to anticipate any disturbing influences.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station = 17° 45' 10"·38

226. Sironj Base-line N.E. End Station [No. (II) of the Great Arc Meridional Series, Section 24° to 30°, volume IV of the *Account of the Operations &c.*] is situated in the lands of the village of Rájpur, pargana Sironj of the territories of the Nawab of Tonk. The circumjacent villages, with their distances and directions, are:—Rájpur 0·7 mile, E.; Tal Barodia 1·5 miles, N.E.; Thanarpur Bimbakeri 1·2 miles, E.S.E.; and Sialpur 1·7 miles, S. The station consists of a pillar of masonry 2 feet high, and 4 feet in diameter, having two mark-stones, one at its upper surface and the other at the bottom.

[The Latitude pillar was built in the prime vertical of the Trigonometrical Station and 50 feet west thereof. The centre of the pillar was within half an inch of the prime vertical. The station lies in the plain to the east of Kaliánpur and

is 1,481 feet above mean sea-level. The plain is perfectly flat and the horizon almost unbroken except to the west where the edge of the plateau rises slightly above it.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $24^{\circ} 8' 53'' \cdot 57$

227. Sirsa Tower Station (No. XL of the Budhon Meridional Series, volume VII of the *Account of the Operations &c.*) is situated on a mound (about 15 feet in height) distant 600 yards north of the village of Sirsa; tahsil and pargana Amroha, district Moradabad. The distances and directions of the surrounding villages are:—Daryapur 0·7 mile, S.W. by W.; Mauye Chak 0·4 mile, N.E. by N.; Raghunáthpur 1 mile, S.E. by S.; and Hāshampur 0·9 mile, N.W. The station consists of a tower of unburnt bricks and mud cement, 14 feet in diameter at top, enclosing a central solid pillar of masonry 26 feet high: it has a mark-stone at summit.

[The Latitude pillar was situated 2077 feet east of the Trigonometrical Station. The azimuth of the latter from the former was  $90^{\circ} 0' 7''$ .—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $28^{\circ} 54' 39'' \cdot 64$

228. Sítápár (or Garhi Húrki) Hill Station (No. XX of the Jabalpur Meridional Series, volume VI of the *Account of the Operations &c.*) is in the tahsil of Tirora and the district of Bhandára of the Central Provinces; it is situated on a hillock, 60 feet high, about half a mile E. by N. of the village of Chichárband. The hillock is 800 yards long, and the Trigonometrical Station is placed at its southern extremity, 400 yards from its centre of gravity.

[For fear that the inequality of matter to the immediate north and south might affect the direction of the plumb-line, the Astronomical Station was built 300 yards due west of the Trigonometrical Station, a site at which the small Sítápár mound could have no appreciable effect. A small northerly attraction should be expected at this station. The northern and eastern horizons are everywhere broken by the Bálághát range. The southern and western horizons are unbroken; but the whole field of view is studded with conical hills 400 feet high, a mile in circumference at their bases and from 5 to 8 miles apart; they should however exercise no appreciable effect on the observations.—S.G.B.]

Geodetic Latitude of the Astronomical Station =  $21^{\circ} 24' 50'' \cdot 54$

229. Sonáda (Sanoda) Tower Station [No. XIX of the Gujarát (Guzerat) Longitudinal Series, volume XIV of the *Account of the Operations &c.*] is situated in the lands of the village of Sonáda, sub-division Dehgám, Baroda (Vadodra) State. It stands on rising ground covered with large trees, about a mile S.E. by E. of Sonáda village on the E. bank of the Khári river, and  $4\frac{3}{4}$  miles S.W. of the town of Dehgám on the road from Ahmedabad to Modása. The directions and distances of the circum-jacent villages are:—Galudan N.W. by N., miles  $1\frac{1}{4}$ ; Vadodra N. by W., miles  $2\frac{3}{4}$ ; Rathoda Vāsna E. by N., miles  $2\frac{3}{4}$ ; Jalundra Mota S.E., miles  $1\frac{1}{4}$ ; and Jhánk S.W. by S., miles 2. The station consists of a tower enclosing a solid pillar of masonry, having a mark-stone in its upper surface and others below at every 5 feet. Four small pillars, with marks thereon, are built around the tower, and the intersection of the lines joining these marks indicates the position of the upper mark on the central pillar.

[Sonáda Astronomical Station was built on the prime vertical of the Trigonometrical Station, about 100 yards west of the latter. It could not be made coincident with the Trigonometrical Station, because the latter is a high brick tower. The country is absolutely flat and no hills are to be seen. Owing to large numbers of big trees, one's view is however much circumscribed on all sides. There is no apparent cause for a deflection of the plumb-line.—S.G.B.]

Geodetic Latitude of the Astronomical Station =  $23^{\circ} 7' 19'' \cdot 89$

230. St. Thomas's Mount Trestle Station (No. XLIV of the Madras Longitudinal Series, volume XIII of the *Account of the Operations &c.*) is situated in the taluk of Saidapet, district Chingleput. It is in the N.W. corner of the terrace of the Portuguese (Roman Catholic) Chapel of St. Thomas which stands on the well-known mount so called, distant 8 miles S.W. of Fort St. George, and 1·3 and 0·8 miles respectively W. by S. and N.W. of the Railway station of Guindy (Kandi) and St. Thomas's Mount. The station is 50 yards W. of the signal flag-staff and 19 yards N.W. of the N.W. corner of the chapel. The station consists of a large slab of stone  $3\frac{1}{2}$  feet in diameter laid down flush with the ground level, on the upper surface of this stone in addition to the usual circle and dot, a broad arrow and the letters G.T.S. are also engraved.

[The Astronomical Station is coincident with the Trigonometrical Station, which is situated on the N.W. corner of the flat-topped hill, called St. Thomas's Mount. The mount is about 250 feet above the surrounding country; there are a few unimportant hills to the S.W., but as these are not less than 2 miles distant no deviation of the plumb-line is to be apprehended: possibly there may be some little attraction towards the south owing to the station not being centrally placed on the hill.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $13^{\circ} 0' 14'' \cdot 79$

231. **Súrantál Hill Station** [No. (III) of the Great Arc Meridional Series, volume IV of the *Account of the Operations &c.*] is situated in pargana Sironj of the territories of the Nawab of Tonk, and stands on the highest swell of an extensive range of flat hills running north and south. The circumjacent villages, with their distances and directions are:—Súrantál about 2 miles, N.N.E.; Bemakheri about  $1\frac{1}{2}$  miles, S.W.; and Sareko about 2 miles, S.S.W. The station consists of a solid pillar, having the usual mark-stone at top.

[The Latitude pillar is situated 39 feet  $11\frac{1}{2}$  inches east of the Trigonometrical Station on an azimuth of  $269^{\circ} 52'$ , so that the latitudes of the two may be considered identical. It is from a point very near this station that the edge of the Kaliánpur plateau bends towards the east.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $24^{\circ} 14' 20''\cdot42$

232. **Telu Hill Station** (No. LI of the Jodhpore Meridional Series, volume IVA of the *Account of the Operations &c.*) is situated in thána Maujgarh, pargana and state Baháwalpur. It is on a sand rise of ground hardly to be called a hill, about 6 miles N. of Bhiawala tank and 7.77 miles S.E. of Maujgarh town. There are two old mud towers near Telu from which the station takes its name, distant  $0\cdot55$  of a mile at an azimuth of  $86^{\circ} 16'$ . Water is obtained from either Bhiawala or Maujgarh. The azimuth and distance of Gidarwala village are  $180^{\circ} 45'$ , miles 2.37. The station consists of a solid pillar 5 feet high with 2.5 feet foundation, having three mark-stones, one at the bottom of the foundation, the second  $2\frac{1}{2}$  feet above it flush with the hill top and the third 5 feet above the second at the surface of the pillar.

[The Astronomical Station was coincident with the Trigonometrical Station. It is situated in a perfectly flat sandy desert.—S.G.B.]

Geodetic Latitude of the Astronomical Station =  $28^{\circ} 56' 11''\cdot34$

233. **Thob Hill Station** (No. VIII of the Jodhpore Meridional Series, volume IVA of the *Account of the Operations &c.*) is situated on a low hill, about half a mile W. of the large village of Thob and 10 miles N. of Pachbudra village, in taluk Siwána of the Jodhpur territories. There is a well of fairly good water near the village. The azimuths and distances of the circumjacent villages are:—Havadhan Roáro  $35^{\circ}$ , miles 2.95; Thob  $266^{\circ}$ , mile 0.63; and Roáro  $348^{\circ}$ , miles 2.22. The station consists of a solid pillar, having two marks, one in the foundation, flush with the hill top and the other in the surface of the pillar which is 3 feet high.

[The Astronomical Station is coincident with the Trigonometrical Station. It is situated on the highest point of a hill of rock, rising 500 feet out of the plain. The southern horizon is broken by the Nagar Hills; peaks Bhadrájan and Kundol are visible. The northern horizon is unbroken. The whole country round is a flat desert plain. There is no apparent cause for deflection of plumb-line.—S.G.B.]

Geodetic Latitude of the Astronomical Station =  $26^{\circ} 3' 5''\cdot85$

234. **Tinsia Hill Station** (No. III of the Karachi Longitudinal Series, volume III of the *Account of the Operations &c.*) is situated in the Tonk territory on the western border of the Sironj district, half a mile S. of the small village of Tinsia, and 5 miles W.S.W. of Isarwús. The station consists of a solid pillar, having mark-stones at top and bottom. It was repaired in 1870 and mark-stones were inserted which are probably within 1 foot of the true positions.

[The Latitude pillar is 39 feet east of the new Trigonometrical Station and on the prime vertical of the latter. The station is surrounded by dense jungle, but is not far from a track which runs from Sironj to the valley of Parbatti.—G.P.L.C.]

Geodetic Latitude of the Astronomical Station =  $24^{\circ} 6' 27''\cdot97$

235. **Tonglu Hill Station** (a secondary station of the North-East Longitudinal Series) is on a lofty mountain, situated on the boundary line between Sikkim and Nepal. At a distance it bears an aspect of a flat-topped cliff, but the summit is composed of three knobs or hillocks, whereof the north-western is the highest. There is a pond in the hollow between the centre and northern summits. Boundary pillar No. 17 stands 33 feet from the station in the direction of Kanchanjanga, and the travellers' bungalow is about 250 yards to the north-west. The station consists of a solid pillar containing a mark-stone and surrounded by a masonry platform.

[The Latitude observations were taken from the Trigonometrical Station. In the case of this station, on account of the distances of the masses, their enormous size and the absence of any experience in respect to stations so situated, it was impossible to form any opinion of the deflection of the plumb-line to be expected. The configuration of the ground in the immediate vicinity is not such as would lead one to suppose any appreciable local disturbance.—H.M.C.]

Geodetic Latitude of the Astronomical Station =  $27^{\circ} 1' 53''\cdot54$

236. Vánákonda Hill Station (No. IX of the Bider Longitudinal Series, volume VI of the *Account of the Operations &c.*) is situated in taluk Warangal, sar-taluk Khamamet of the Nizam's territories. It is on a conspicuous hill surrounded by isolated hillocks distant from it about 6 miles. The azimuths and distances of the circumjacent villages are:—Mádápur  $165^{\circ} 47'$ , miles 1.13; Isnúr  $231^{\circ} 18'$ , miles 3.21; Darmápur  $330^{\circ} 21'$ , miles 1.58. The station consists of a solid pillar, having two marks, the upper 2.46 feet above the lower which is engraved on the rock *in situ*.

[The Astronomical Station is identical with the Trigonometrical Station. This is situated on a high hill, about 700 feet above the surrounding country, there are a few similar isolated hills in the neighbourhood, but no deviation of the plumb-line is to be anticipated on their account. With regard to the position of the station with respect to the mass of the hill itself it is probable that the centre of attraction is somewhat south of it, but only slightly so, if at all, so that the situation may be regarded as favourable.—G.P.L.C.]

$$\text{Geodetic Latitude of the Astronomical Station} = 17^{\circ} 36' 6''.87$$

237. Virária Hill Station (No. LXVII of the Karachi Longitudinal Series, volume III of the *Account of the Operations &c.*) is situated on a sand-hill in that portion of the Thar or Little-desert, which appertains to Bhúj. The large village of Jharpa is distant about 3 miles. The station consists of a solid pillar, having three mark-stones.

[The Astronomical Station is 1896 feet west and 11.95 feet south of the Trigonometrical Station of the same name. The country is rugged in appearance—the sand-hills being very steep and water-worn. In general the height of these hills from trough to crest is from 150 to 300 feet. The top of the Trigonometrical Station was found to have been destroyed but the rest was in good condition. The Trigonometrical pillar was found with difficulty as it had been covered by drifting sand to a depth of about 2 feet.—H.M.C.]

$$\text{Geodetic Latitude of the Trigonometrical Station} = 24^{\circ} 56' 36''.25$$

$$\text{Reduction to Astronomical Station} = - 0.12$$

$$\text{Geodetic Latitude of the Astronomical Station} = 24 \quad 56 \quad 36.13$$

238. Vizagapatam Base-line North End Station (No. LXVIII of the East Coast Series, volume VI of the *Account of the Operations &c.*) is situated in the Srungarapúkota taluk of Vizagapatam district, about 1000 yards S.S.E. of the village of Rámbhadrápúram-Agraharam, and about 3 miles west of Alamanda Railway station. The station consists of a solid pillar of masonry, having 3 circular mark-stones, 38 inches in diameter by 6 inches thick, the lowermost resting about 2 feet from the bottom and the two others in order vertically at intervals of 3 inches apart. Above the ground level there is a platform of cut-stone masonry, 8 feet square and 1 foot high, reaching to the edge of the annulus, there is also a fourth mark-stone resting over the others and separated from the nearest by a 6-inch layer of masonry. A pyramidal stone cap about 20 inches square by 15 inches high hollowed out at the base, protects the uppermost mark and a cut-stone masonry dome rises to the height of about 12 feet over the station.

[The Astronomical Station is 137 feet 7 inches to the east of the Trigonometrical Station; it is  $0^{\circ} 46'$  out of the prime vertical; i.e. it is 1.84 feet north of its proper position. The surrounding country has very gradual undulations and the Trigonometrical Station is on the highest point in the vicinity. The sea-coast runs in a N.E.-S.W. direction and its nearest point is 17 miles S.W. of the station. The Eastern Gháts run roughly parallel to the sea-coast, and are at their nearest point 15 miles N.E. of the station. Peaks in the vicinity are 3000 to 4000 feet high; these hills probably exert an N.E. attraction but this would be counteracted by a mass of low hills S.E. and S. of the station. The resultant attraction should be very small.—E.A.T.]

$$\text{Geodetic Latitude of the Trigonometrical Station} = 18^{\circ} 1' 2''.91$$

$$\text{Reduction to Astronomical Station} = + 0.02$$

$$\text{Geodetic Latitude of the Astronomical Station} = 18 \quad 1 \quad 2.93$$

239. Waltair Longitude Station (*vide* volume XV of the *Account of the Operations &c.*) is situated in the enclosure of Narsing Rao's house, and lies 95.50 feet east, and 44.25 feet south of the western end of the gable of the house.

[The Latitude Station is identical with the Longitude Station. The presence of the Demru-Simachilum range to the north makes a deviation of the plumb-line in this direction probable. In other respects the situation is favourable.—G.P.L.C.]

$$\text{Geodetic Latitude of the Latitude Station} = 17^{\circ} 43' 29''.31$$

*Summary.*

No. of pairs 24

No. of observations 40

Mean difference between observations taken E, W and those taken W, E =  $-0''.81$ Observed Co-latitude (weighted mean)  $62^{\circ} 50' 18''.55 \pm 0''.091$ Correction for Height above Sea-level +  $0''.02$ **Final Co-latitude  $62^{\circ} 50' 18''.57$** 

° ' "

Astronomical Latitude (A) = 27 9 41.43  $\pm 0.091$ 

Geodetic Latitude (G) = 27 9 45.86

Deflection of plumb-line (A-G) = - 4.43

117. Agra Longitude station, 1st visit—Co-latitude  $62^{\circ} 50' +$ Latitude  $27^{\circ} 10'$ 

Instrument—Zenith Sector No. 1 used as Zenith Telescope

Longitude  $78^{\circ} 3'$ Mean Height of Barometer  $29^{\text{in}}.34$ Height  $550$  feetMean Temperature  $63^{\circ}.1$ 

Observer—Captain S. G. Burrard, R.E.

*Summary.*

No. of pairs 43

No. of observations 77

Mean difference between observations taken E, W and those taken W, E =  $-0'' \cdot 04$ Observed Co-latitude (weighted mean)  $62^{\circ} 50' 25'' \cdot 49 \pm 0'' \cdot 061$ Correction for Height above Sea-level +  $0'' \cdot 02$ Corrected Co-latitude  $62^{\circ} 50' 25'' \cdot 51 \pm 0'' \cdot 061$ *For final Co-latitude and deduction of (A - G) see 2nd visit.*

117. Agra Longitude station, 2nd visit—Co-latitude  $62^{\circ} 50' +$ Latitude ...  $27^{\circ} 10'$ 

Instrument—Zenith Telescope

Longitude ... 78 3

Mean Height of Barometer  $29.27$  in.

Height ... 550 feet

Mean Temperature  $69^{\circ}.9$ 

Observers—Captain G. P. Lenox Conyngham, R.E. and Lieut. G. A. Beazeley, R.E.

Summary.

No. of pairs 58

No. of observations 108

Mean difference between observations taken E, W and those taken W, E =  $+ 0''.03$ Observed Co-latitude (weighted mean)  $65^{\circ} 10' 29''.50 \pm 0''.034$ Correction for Height above Sea-level  $+ 0''.00$ **Final Co-latitude  $65^{\circ} 10' 29''.50$** 

0 / " "

Astronomical Latitude (A) = 24 49 30.50  $\pm 0.034$ 

Geodetic Latitude (G) = 24 49 31.23

Deflection of plumb-line (A-G) = - 0.73

123. Algi—Co-latitude  $64^{\circ} 30' +$ Latitude ...  $25^{\circ} 30'$ 

Instrument—Zenith Telescope

Longitude ... 78 24

Mean Height of Barometer 29.11 in.

Height ... 854 feet

Temperature

 $59^{\circ}.1$ 

Observer—Licut. H. M. Cowie, R. E.

*Summary.*

No. of pairs 34

No. of observations 109

Mean difference between observations taken E, W and those taken W, E =  $-0''\cdot11$ Observed Co-latitude (weighted mean)  $64^{\circ} 30' 11''\cdot81 \pm 0''\cdot038$ Correction for Height above Sea-level +  $0''\cdot03$ **Final Co-latitude  $64^{\circ} 30' 11''\cdot84$** 

° ' " "

Astronomical Latitude (A) = 25 29 48'16  $\pm 0'038$ 

Geodetic Latitude (G) = 25 29 46'19

Deflection of plumb-line (A-G) = + 1'97

124. Amritsar—Co-latitude  $58^{\circ} 21' +$ Latitude ...  $31^{\circ} 38'$ 

Instrument—Zenith Sector No. 1 used as Zenith Telescope

Longitude . . .  $74^{\circ} 55'$ Mean Height of Barometer  $29^{\text{in.}} 13$ 

Height ... 770 feet

Mean Temperature  $61^{\circ} 2$ 

Observer—Captain S. G. Burrard, R.E.

*Summary.*

No. of pairs 32

No. of observations 108

Mean difference between observations taken E, W and those taken W, E =  $+ 0''.09$ Observed Co-latitude (weighted mean)  $61^{\circ} 26' 36''.69 \pm 0''.050$ Correction for Height above Sea-level  $+ 0''.03$ Final Co-latitude  $61^{\circ} 26' 36''.72$ Astronomical Latitude (A) = 28 33 23.28  $\pm 0.050$ 

Geodetic Latitude (G) = 28 33 28.08

Deflection of plumb-line (A-G) = - 4.80

131. Bhaorasa—Co-latitude  $65^{\circ} 51' +$ Latitude ...  $24^{\circ} 8'$ 

Instrument—Zenith Sector No. 1 used as Zenith Telescope

Longitude ...  $78 3$ Mean Height of Barometer  $28.63$   
in.

Height ... 1387 feet

Mean Temperature  $67^{\circ}.0$ 

Observer—Captain G. P. Lenox Conyngham, R.E.

*Summary.*

No. of pairs 40

No. of observations 75

Mean difference between observations taken E, W and those taken W, E =  $+ 0''.21$ Observed Co-latitude (weighted mean)  $65^{\circ} 51' 54''.82 \pm 0''.134$ Correction for Height above Sea-level  $+ 0''.05$ **Final Co-latitude  $65^{\circ} 51' 54''.87$** 

o ' " "

Astronomical Latitude (A) = 24 8  $5.13^{\circ} \pm 0.134$ 

Geodetic Latitude (G) = 24 8 3.74

Deflection of plumb-line (A—G) = + 1.39

132. Bhimsain—Co-latitude  $69^{\circ} 2' +$ 

Latitude ...  $20^{\circ} 58'$  Maximum recorded Height of Barometer = 28.716 in.  
 Longitude ... 79 49 Minimum " " " = 28.663  
 Height ... 1490 feet Maximum " Reading of Thermometer =  $76^{\circ} \cdot 8$   
 Instrument—Zenith Sector No. 2 Minimum " " " = 62.0

Observer—Lieut. S. G. Burrard, R.E.

*Summary.*

No. of North Stars 34      •      No. of South Stars 34  
No. of observations 134

Co-latitude by North Stars      69 2 31 264     $\pm$  0 062  
 „      „      South      „      69 2 31 546     $\pm$  0 065  
 Mean Co-latitude      69 2 31 405     $\pm$  0 045

Correction for Height above Sea-level      + 0 05

**Final Co-latitude       $69^{\circ} 2' 31'' \cdot 455$**

Astronomical Latitude (A)      = 20 57 28 545     $\pm$  0 045  
 Geodetic Latitude (G)      = 20 57 35 96  
 Deflection of plumb-line (A-G)      =      - 7 42

133. Birond—Co-latitude  $60^{\circ} 45' +$ Latitude ...  $29^{\circ} 15'$ 

Instrument—Zenith Telescope

Longitude ...  $79^{\circ} 45'$ Mean Height of Barometer  $22.90$  in.

Height ... 6967 feet

Mean Temperature  $45^{\circ}.8$ 

Observer—Lieut. H. M. Cowie, R.E.

Summary.

No. of pairs 16

No. of observations 51

Mean difference between observations taken E, W and those taken W, E = + 0".02

Observed Co-latitude (weighted mean)  $60^{\circ} 45' 29''.97 \pm 0''.052$ 

Correction for Height above Sea-level + 0".31

**Final Co-latitude  $60^{\circ} 45' 30''.28$** Astronomical Latitude (A) = 29 14 29.72  $\pm 0.052$ 

Geodetic Latitude (G) = 29 15 14.15

Deflection of plumb-line (A-G) = - 44.43

134. Bithnok—Co-latitude  $62^{\circ} 6' +$ Latitude ...  $27^{\circ} 53'$ 

Instrument—Zenith Sector No. 1 used as Zenith Telescope

Longitude ...  $72^{\circ} 42'$ Mean Height of Barometer  $29.18$  in.

Height ... 774 feet

Mean Temperature  $62^{\circ} 9'$ 

Observer—Captain S. G. Burrard, R.E.

Summary.

No. of pairs 45

No. of observations 85

Mean difference between observations taken E, W and those taken W, E =  $+ 0''.29$ Observed Co-latitude (weighted mean)  $62^{\circ} 6' 35''.00 \pm 0''.055$ Correction for Height above Sea-level  $+ 0''.03$ Final Co-latitude  $62^{\circ} 6' 35''.03$ 

Astronomical Latitude (A)	$= 27 \ 53 \ 24.97 \pm 0.055$
---------------------------	-------------------------------

Geodetic Latitude (G)	$= 27 \ 53 \ 22.03$
-----------------------	---------------------

Deflection of plumb-line (A-G)	$= + \ 2.94$
--------------------------------	--------------

135. Bolarum—Co-latitude  $72^{\circ} 29' +$ Latitude ...  $17^{\circ} 30'$ 

Instrument—Zenith Telescope

Longitude ...  $78^{\circ} 34'$ Mean Height of Barometer  $28^{\circ} 22'$  in.

Height ... 1971 feet

Mean Temperature  $53^{\circ} 3'$ 

Observer—Captain G. P. Lenox Conyngham, R.E.

## Summary.

No of pairs 47

No. of observations 84

Mean difference between observations taken E, W and those taken W, E =  $-0''.05$ Observed Co-latitude (weighted mean)  $72^{\circ} 29' 52''.56 \pm 0''.060$ Correction for Height above Sea-level +  $0''.08$ Final Co-latitude  $72^{\circ} 29' 52''.64$ Astronomical Latitude (A) =  $17^{\circ} 30' 7.36 \pm 0.060$ Geodetic Latitude (G) =  $17^{\circ} 30' 13.41$ Deflection of plumb-line (A-G) =  $-6.05$

136. Bolikonda—Colatitude  $72^{\circ} 17' +$ 

Latitude ...  $17^{\circ} 43'$  Maximum recorded Height of Barometer = 28.764 in.  
 Longitude ... 79 50 Minimum " " " = 28.520  
 Height ... 1363 feet Maximum " Reading of Thermometer =  $86^{\circ} 0$   
 Instrument—Zenith Sector No. 2 Minimum " " " = 72.0

Observer—J. Eccles, M. A.

Note.—The barometer was read during work every hour, the thermometer every fifteen minutes. For the calculations of refraction a separate value for the pressure and temperature was deduced for each star.

*Summary.*

No. of North Stars 39                      No. of South Stars 35  
 No. of observations 204

Co-latitude by North Stars    72 17 31.31  $\pm$  0.060  
 „ „ South „                    72 17 30.44  $\pm$  0.059  
 Mean Co-latitude               72 17 30.88  $\pm$  0.042

Correction for Height above Sea-level                      + 0.04

**Final Co-latitude  $72^{\circ} 17' 30'' \cdot 92$**

Astronomical Latitude (A)                      = 17 42 29.08  $\pm$  0.042  
 Geodetic Latitude (G)                          = 17 42 35.82  
 Deflection of plumb-line (A-G)               =       -    6.74

137. Bostan—Co-latitude  $61^{\circ} 29' +$ Latitude ...  $28^{\circ} 31'$ 

Instrument—Zenith Sector No. 1 used as zenith telescope

Longitude ...  $77^{\circ} 33'$ 

Mean Height of Barometer 29.29

Height ... 758 feet

Mean Temperature  $50^{\circ}.1$ 

Observer—Captain G. P. Lenox Conyngham, R.E.

*Summary.*

No. of pairs 32  
No. of observations 106

Mean difference between observations taken E, W and those taken W, E = + 0".33

Observed Co-latitude (weighted mean)  $61^{\circ} 29' 5''.72 \pm 0''.060$

Correction for Height above Sea-level + 0".03

**Final Co-latitude  $61^{\circ} 29' 5''.75$**

Astronomical Latitude (A) =  $28^{\circ} 30' 54''.25 \pm 0.060$

Geodetic Latitude (G) =  $28^{\circ} 30' 59''.64$

Deflection of plumb-line (A-G) = - 5.39

138. Budhon—Co-latitude  $65^{\circ} 54' +$ Latitude ...  $24^{\circ} 5'$ 

Instrument—Zenith Telescope

Longitude ...  $78^{\circ} 34'$ 

Mean Height of Barometer 28.21 in.

Height ... 1867 feet

Mean Temperature  $62^{\circ} 0$ 

Observer—Lieut. H. M. Cowie, R.E.

Summary.

No. of pairs 35

No. of observations 127

Mean difference between observations taken E, W and those taken W, E =  $-0''.03$ Observed Co-latitude (weighted mean)  $65^{\circ} 54' 50''.94 \pm 0''.034$ Correction for Height above Sea-level +  $0''.07$ Final Co-latitude  $65^{\circ} 54' 51''.01$ 

° ' "

Astronomical Latitude (A) = 24 5 8.99  $\pm 0.034$ 

Geodetic Latitude (G) = 24 5 8.41

Deflection of plumb-line (A-G) = + 0.58

139. Burgpaili—Co-latitude  $71^{\circ} 5' +$ 

*Latitude* ...  $18^{\circ} 54'$       *Maximum recorded Height of Barometer* =  $29^{\circ} 156^{\text{in.}}$   
*Longitude* ...  $79^{\circ} 44'$       *Minimum* " " " =  $28^{\circ} 916$   
*Height* ... 983 feet      *Maximum* " *Reading of Thermometer* =  $80^{\circ} 5$   
*Instrument*—Zenith Sector No. 2      *Minimum* " " " =  $64^{\circ} 5$

Observer—J. Eccles, M. A.

Note.—The barometer was read during work every hour, the thermometer every fifteen minutes. For the calculations of refraction a separate value for the pressure and temperature was deduced for each star.

*Summary.*

No of pairs 34

No. of observations 92

Mean difference between observations taken E, W and those taken W, E =  $-0'' 01$ Observed Co-latitude (weighted mean)  $61^{\circ} 54' 59'' 26 \pm 0'' 019$ Correction for Height above Sea-level +  $0'' 03$ **Final Co-latitude  $61^{\circ} 54' 59'' 29$** 

Astronomical Latitude (A) = 28 5 0.71  $\pm 0.049$

Geodetic Latitude (G) = 28 5 1.59

Deflection of plumb-line (A-G) = - 0.88

142. Chandipur—Co-latitude  $68^{\circ} 33' +$ Latitude ...  $21^{\circ} 27'$ 

Instrument—Zenith Telescope

Longitude ... 87 5

Mean Height of Barometer 29.83

Height ... 53 feet

Mean Temperature  $75^{\circ}.3$ 

Observer—Lieut. E. A. Tandy, R.E.

*Summary.*

No. of pairs 49

No. of observations 95

Mean difference between observations taken E, W and those taken W, E =  $-0''.54$ Observed Co-latitude (weighted mean)  $68^{\circ} 33' 25''.97 \pm 0''.061$ Correction for Height above Sea-level  $0''.00$ **Final Co-latitude  $68^{\circ} 33' 25''.97$** Astronomical Latitude (A) =  $21^{\circ} 26' 34''.03 \pm 0''.061$ Geodetic Latitude (G) =  $21^{\circ} 26' 36''.99$ Deflection of plumb-line (A-G) =  $- 2''.96$

143. Chanduria—Co-latitude  $64^{\circ} 15' +$ Latitude ...  $25^{\circ} 44'$ 

Instrument—Zenith Telescope

Longitude ... 88 25

Mean Height of Barometer  $29.87$  in.

Height ... 160 feet

Mean Temperature  $50^{\circ}.1$ 

Observer—Lieut. H. M. Cowie, R.E.

*Summary.*

No. of pairs 50

No. of observations 100

Mean difference between observations taken E, W and those taken W, E =  $- 0''\cdot02$ Observed Co-latitude (weighted mean)  $65^{\circ} 7' 14''\cdot63 \pm 0''\cdot051$ Correction for Height above Sea-level +  $0''\cdot01$ **Final Co-latitude  $65^{\circ} 7' 14''\cdot64$** 

° ' "

 Astronomical Latitude (A) = 24 52 45'36  $\pm 0\cdot051$ 

Geodetic Latitude (G) = 24 52 43'95

Deflection of plumb-line (A-G) = + 1'41

147. Colaba—Co-latitude  $71^{\circ} 6' +$ Latitude ...  $18^{\circ} 54'$ 

Instrument—Zenith Telescope

Longitude ...  $72^{\circ} 51'$ Mean Height of Barometer  $30.01$  in.

Height ... 75 feet

Mean Temperature  $72^{\circ}.9$ 

Observer—Lieut. G. P. Lenox Conyngham, R.E.

*Summary.*

No. of pairs 39

No. of observations 74

Mean difference between observations taken E, W and those taken W, E = + 0".03

Observed Co-latitude (weighted mean)  $71^{\circ} 6' 20''.85 \pm 0''.061$ 

Correction for Height above Sea-level 0".00

**Final Co-latitude  $71^{\circ} 6' 20''.85$** 

° ' "

Astronomical Latitude (A) = 18 53 39.15  $\pm 0.061$ 

Geodetic Latitude (G) = 18 53 49.48

Deflection of plumb-line (A-G) = - 10.33

148. Cuttack—Co-latitude  $69^{\circ} 31' +$ Latitude ...  $20^{\circ} 29'$ 

Instrument—Zenith Telescope

Longitude ...  $85^{\circ} 54'$ Mean Height of Barometer  $29^{\text{in.}} 57$ 

Height ... 133 feet

Mean Temperature  $73^{\circ} 1$ 

Observer—Lieut. E. A. Tandy, R.E.

## Summary.

No. of pairs 59

No. of observations 124

Mean difference between observations taken E, W and those taken W, E =  $-0''.81$ Observed Co-latitude (weighted mean)  $69^{\circ} 31' 7''.95 \pm 0''.048$ Correction for Height above Sea-level  $0''.00$ Final Co-latitude  $69^{\circ} 31' 7''.95$ Astronomical Latitude (A) =  $20 \ 28 \ 52.05 \pm 0.048$ Geodetic Latitude (G) =  $20 \ 29 \ 0.68$ Deflection of plumb-line (A-G) =  $- \ 8.63$

149. Daiadhari—Co-latitude  $65^{\circ} 21' +$ Latitude ...  $24^{\circ} 38'$ 

Instrument—Zenith Sector No 1 used as Zenith Telescope

Longitude ...  $77^{\circ} 42'$ Mean Height of Barometer  $28.10^{\text{in.}}$ 

Height ... 1867 feet

Mean Temperature  $68^{\circ}.0'$ 

Observer—Captain G. P. Lenox Conyngham, R.E.

Summary.

No. of pairs 41

No. of observations 80

Mean difference between observations taken E, W and those taken W, E =  $-0''.71$

Observed Co-latitude (weighted mean)  $65^{\circ} 21' 41''.14 \pm 0''.124$

Correction for Height above Sea-level +  $0''.07$

Final Co-latitude  $65^{\circ} 21' 41''.21$

Astronomical Latitude (A) =  $24^{\circ} 38' 18.79'' \pm 0.124$

Geodetic Latitude (G) =  $24^{\circ} 38' 17.59''$

Deflection of plumb-line (A-G) = +  $1.20''$

150. Dalea—Co-latitude  $67^{\circ} 40' +$ Latitude ...  $22^{\circ} 20'$ 

Instrument—Zenith Telescope

Longitude ... 82 4

Mean Height of Barometer  $28^{\text{in}}.14$ 

Height ... 1622 feet

Mean Temperature  $83^{\circ} 9$ 

Observer—Lieut. E. A. Tandy, R.E.

Summary.

No. of pairs 45

No. of observations 172

Mean difference between observations taken E, W and those taken W, E =  $-0''.32$ Observed Co-latitude (weighted mean)  $74^{\circ} 3' 60''.31 \pm 0''.052$ Correction for Height above Sea-level  $0''.00$ **Final Co-latitude  $74^{\circ} 3' 60''.31$** 

	° ' "	"
Astronomical Latitude (A)	= 15 55 59.69	$\pm 0.052$

Geodetic Latitude (G)	= 15 56 0.14
-----------------------	--------------

Deflection of plumb-line (A-G)	= - 0.45
--------------------------------	----------

152. Dargawa—Co-latitude  $65^{\circ} 22' +$ Latitude ...  $24^{\circ} 37'$ 

Instrument—Zenith Telescope

Longitude ...  $79^{\circ} 4'$ Mean Height of Barometer  $28.90^{\text{in.}}$ 

Height ... 1152 feet

Mean Temperature  $61^{\circ}.8$ 

Observer—Lieut. H. M. Cowie, R. E.

*Summary.*

No. of pairs 28

No. of observations 188

Mean difference between observations taken E, W and those taken W, E =  $-0''.03$ Observed Co-latitude (weighted mean)  $65^{\circ} 22' 42''.63 \pm 0''.040$ Correction for Height above Sea-level +  $0''.05$ Final Co-latitude  $65^{\circ} 22' 42''.68$ Astronomical Latitude (A) =  $24 \ 37 \ 17.32 \pm 0.040$ Geodetic Latitude (G) =  $24 \ 37 \ 13.21$ Deflection of plumb-line (A-G) =  $+ 4.11$

153. Dariapur—Co-latitude  $68^{\circ} 12' +$ Latitude ...  $21^{\circ} 47'$ 

Instrument—Zenith Telescope

Longitude ... 87 55

Mean Height of Barometer  $29.74^{\text{in.}}$ 

Height ... 63 feet

Mean Temperature  $78^{\circ} 3$ 

Observer—Lieut. E. A. Tandy, R. E.

Summary.

No. of pairs 51

No. of observations 106

Mean difference between observations taken E, W and those taken W, E = - 0'35

Observed Co-latitude (weighted mean)  $68^{\circ} 12' 31'' \cdot 18 \pm 0'' \cdot 056$ 

Correction for Height above Sea-level 0''00

Final Co-latitude  $68^{\circ} 12' 31'' \cdot 18$ Astronomical Latitude (A) = 21 47 28'82  $\pm 0'056$ 

Geodetic Latitude (G) = 21 47 27'95

Deflection of plumb-line (A-G) = + 0'87

154. Darutippa—Co-latitude  $74^{\circ} 59' +$ Latitude ...  $15^{\circ} 1'$ 

Instrument—Zenith Telescope

Longitude ... 79 57

Mean Height of Barometer  $29^{\circ} 91$  in.

Height ... 195 feet

Mean Temperature  $73^{\circ} 1$ 

Observer—Lieut. G. P. Lenox Conyngham, R.E.

Summary.

No. of pairs 61

No. of observations 121

Mean difference between observations taken E, W and those taken W, E =  $-0''.16$ Observed Co-latitude (weighted mean)  $74^{\circ} 59' 26''.47 \pm 0''.044$ Correction for Height above Sea-level +  $0''.01$ Final Co-latitude  $74^{\circ} 59' 26''.48$ Astronomical Latitude (A) =  $15 \quad 0 \quad 33.52 \pm 0.044$ Geodetic Latitude (G) =  $15 \quad 0 \quad 36.47$ Deflection of plumb-line (A-G) =  $- \quad - \quad 2.95$

155. Deesa—Co-latitude  $65^{\circ} 44' +$ Latitude ..  $24^{\circ} 15'$ 

Instrument—Zenith Sector No. I used as Zenith Telescope

Longitude ..  $72^{\circ} 14'$ Mean Height of Barometer  $29.55^m$ 

Height ... 443 feet

Mean Temperature  $72^{\circ} 0$ 

Observer—Captain S. G. Burrard, R. E.

Summary.

No. of pairs 25

No. of observations 52

Mean difference between observations taken E, W and those taken W, E =  $+ 0''.42$ Observed Co-latitude (weighted mean)  $59^{\circ} 25' 60''.35 \pm 0''.086$ Correction for Height above Sea-level +  $0''.02$ Final Co-latitude  $59^{\circ} 25' 60''.37$ Astronomical Latitude (A) =  $30^{\circ} 33' 59''.63 \pm 0.086$ Geodetic Latitude (G) =  $30^{\circ} 34' 1''.87$ Deflection of plumb-line (A-G) =  $- 2.24$

159. Dhauleshvar—Co-latitude  $71^{\circ} 34' +$ Latitude ...  $18^{\circ} 26'$ 

Instrument—Zenith Telescope

Longitude ...  $74^{\circ} 12'$ Mean Height of Barometer  $27^{\text{in.}} 21$ 

Height ... 2939 feet

Mean Temperature  $66^{\circ} 0$ 

Observer—Lieut. G. P. Lenox Conyngham, R. E.

Summary.

No. of pairs 57

No. of observations 102

Mean difference between observations taken E, W and those taken W, E =  $+ 0''.13$ Observed Co-latitude (weighted mean)  $71^{\circ} 34' 17''.07 \pm 0''.045$ Correction for Height above Sea-level  $+ 0''.09$ **Final Co-latitude  $71^{\circ} 34' 17''.16$** 

o ' " "

Astronomical Latitude (A) = 18 25 42.84  $\pm 0.045$ .

Geodetic Latitude (G) = 18 25 41.64

Deflection of plumb-line (A-G) = + 1.20

160. Dhulipalla—Co-latitude  $73^{\circ} 34' +$ 

Latitude ...  $16^{\circ} 26'$  Maximum recorded Height of Barometer = 29.814<sup>in.</sup>  
 Longitude ... 80 8 Minimum " " " = 29.716  
 Height ... 245 feet Maximum " Reading of Thermometer =  $86^{\circ} \cdot 0$   
 Instrument—Zenith Sector No. 2 Minimum " " " =  $74 \cdot 5$

Observer—J. Eccles, M. A.

Note.—The barometer was read during work every hour, the thermometer every fifteen minutes. For the calculations of refraction a separate value for the pressure and temperature was deduced for each star.

Summary.

No. of pairs 64

No. of observations 111

Mean difference between observations taken E, W and those taken W, E =  $-0''\cdot05$ Observed Co-latitude (weighted mean)  $65^{\circ} 8' 42''\cdot67 \pm 0''\cdot036$ Correction for Height above Sea-level +  $0''\cdot01$ Final Co-latitude  $65^{\circ} 8' 42''\cdot68$ Astronomical Latitude (A) =  $24 51 17\cdot32 \pm 0\cdot036$ Geodetic Latitude (G) =  $24 51 19\cdot36$ Deflection of plumb-line (A-G) =  $- 2\cdot04$

162. Diwai—Co-latitude  $70^{\circ} 10' +$ 

*Latitude* ...  $19^{\circ} 50'$       *Maximum recorded Height of Barometer* =  $29^{\text{in.}} 21.4$   
*Longitude* ...  $79^{\circ} 35'$       *Minimum* " " " =  $29.082$   
*Height* ... 967 feet      *Maximum* " *Reading of Thermometer* =  $74^{\circ}.8$   
*Instrument*—Zenith Sector No. 2      *Minimum* " " " =  $64.0$

Observer—J. Eccles, M.A.

Summary.

No. of North Stars 44      No. of South Stars 30  
 No. of observations 204

Co-latitude by North Stars      70 10 33.66  $\pm$  0.073

„ „ South Stars      70 10 32.54  $\pm$  0.079

Mean Co-latitude      70 10 33.10  $\pm$  0.054

Correction for Height above Sea-level      + 0.03

Final Co-latitude      70° 10' 33".13

Astronomical Latitude (A)      = 19 49 26.87  $\pm$  0.054

Geodetic Latitude (G)      = 19 49 32.57

Deflection of plumb-line (A - G)      = - 5.70

163. Gudali—Co-latitude  $75^{\circ} 58' +$ Latitude ...  $14^{\circ} 1'$ 

Instrument—Zenith Telescope

Longitude ...  $80^{\circ} 4'$ Mean Height of Barometer  $29.80^{\text{in.}}$ 

Height ... 292 feet

Mean Temperature  $72^{\circ}.4$ 

Observer—Lieut. G. P. Lenox Conyngham, R. E.

Summary.

No. of pairs 29

No. of observations 70

Mean difference between observations taken E, W and those taken W, E =  $+ 0'' \cdot 21$ Observed Co-latitude (weighted mean)  $70^{\circ} 8' 17'' \cdot 31 \pm 0'' \cdot 078$ Correction for Height above Sea-level +  $0'' \cdot 09$ **Final Co-latitude  $70^{\circ} 8' 17'' \cdot 40$** 

	° ' "	"
Astronomical Latitude (A)	= 19 51 42 60	$\pm 0 \cdot 078$

Geodetic Latitude (G)	= 19 51 42 34
-----------------------	---------------

Deflection of plumb-line (A-G)	= + 0 26
--------------------------------	----------

166. Jalpaiguri—Co-latitude  $63^{\circ} 28' +$ Latitude ...  $26^{\circ} 31'$ 

Instrument—Zenith Telescope

Longitude ... 88 47

Mean Height of Barometer 29.64 in.

Height ... 280 feet

Mean Temperature  $58^{\circ} 9$ 

Observer—Lieut. H. M. Cowie, R.E.

Summary.

No. of pairs 44

No. of observations 87

Mean difference between observations taken E, W and those taken W, E =  $-0''.28$ Observed Co-latitude (weighted mean)  $65^{\circ} 52' 49''.46 \pm 0''.079$ Correction for Height above Sea-level +  $0''.07$ Final Co-latitude  $65^{\circ} 52' 49''.53$ Astronomical Latitude =  $24^{\circ} 7' 10''.47 \pm 0''.079$ This value was corrected for variation of latitude and printed on p. (34) as  $24^{\circ} 7' 10''.59$ .

For other five values of the Astronomical Latitude see pp. (33) and (34).

169. Kamkhera—Co-latitude  $66^{\circ} 0' +$ Latitude ...  $24^{\circ} 0'$ 

Instrument—Zenith Sector No. 1 used as Zenith Telescope

Longitude ...  $77^{\circ} 46'$ Mean Height of Barometer  $28.09$  in.

Height ... 1780 feet

Mean Temperature  $68^{\circ} 0'$ 

Observer—Captain G. P. Lenox Conyngham, R.E.

*Summary.*

No. of pairs 42  
No. of observations 84

Mean difference between observations taken E, W and those taken W, E =  $+ 0''.02$

Observed Co-latitude (weighted mean)  $66^{\circ} 0' 17''.04 \pm 0''.069$

Correction for Height above Sea-level  $+ 0''.07$

**Final Co-latitude  $66^{\circ} 0' 17''.11$**

	° ' "	
Astronomical Latitude (A)	= 23 59 42.89	$\pm 0.069$
Geodetic Latitude (G)	= 23 59 44.93	
Deflection of plumb-line (A-G)	= - 2.04	

170. Kanheri—Co-latitude  $71^{\circ} 30' +$ Latitude ...  $18^{\circ} 30'$ 

Instrument—Zenith Telescope

Longitude ...  $75^{\circ} 46'$ Mean Height of Barometer  $27^{\circ} 42'$ 

Height ... 2610 feet

Mean Temperature  $66^{\circ} 0'$ 

Observer—Lieut. G. P. Lenox Conyngham, R.E.

Summary.

No. of pairs 61

No. of observations 103

Mean difference between observations taken E, W and those taken W, E = + 0".20

Observed Co-latitude (weighted mean)  $71^{\circ} 30' 38''.08 \pm 0''.050$ 

Correction for Height above Sea-level + 0".08

**Final Co-latitude  $71^{\circ} 30' 38''.16$** 

Astronomical Latitude (A)	=	18	29	21.84	$\pm 0.050$
---------------------------	---	----	----	-------	-------------

Geodetic Latitude (G)	=	18	29	30.75	
-----------------------	---	----	----	-------	--

Deflection of plumb-line (A-G)	=	-	8.91	
--------------------------------	---	---	------	--

171. Karia—Co-latitude  $70^{\circ} 47' +$ Latitude ...  $19^{\circ} 12'$ 

Instrument—Zenith Telescope

Longitude ... 82 10

Mean Height of Barometer 27.97

Height ... 2014 feet

Mean Temperature  $68^{\circ}.6$ 

Observer—Lieut. E. A. Tandy, R.E.

Summary.

No. of pairs 43

No. of observations 104

Mean difference between observations taken E,W and those taken W, E =  $+ 0''.10$ Observed Co-latitude (weighted mean)  $70^{\circ} 47' 57''.26 \pm 0''.053$ Correction for Height above Sea-level +  $0''.07$ **Final Co-latitude  $70^{\circ} 47' 57''.33$** 

	°	'	"	
Astronomical Latitude (A)	=	19	12	2.67 $\pm 0.053$

Geodetic Latitude (G)	=	19	12	5.98
-----------------------	---	----	----	------

Deflection of plumb-line (A-G)	=	-	3.31
--------------------------------	---	---	------

172. Karothol—Co-latitude  $65^{\circ} 6' +$ Latitude ...  $24^{\circ} 54'$ 

Instrument—Zenith Telescope

Longitude ...  $67^{\circ} 56'$ Mean Height of Barometer  $29.95^{\text{in.}}$ 

Height ... 260 feet

Mean Temperature  $51^{\circ}.1$ 

Observer—Licut. H. M. Cowie, R.E.

Summary.

No. of pairs 50

No. of observations 100

Mean difference between observations taken E, W and those taken W, E = + 0".08

Observed Co-latitude (weighted mean)  $65^{\circ} 6' 15''.21 \pm 0''.028$ 

Correction for Height above Sea-level + 0".01

Final Co-latitude  $65^{\circ} 6' 15''.22$ Astronomical Latitude (A) = 24 53 44.78  $\pm 0.028$ 

Geodetic Latitude (G) = 24 53 46.69

Deflection of plumb-line (A-G) = - 1.91

173. Kaulia—Co-latitude  $62^{\circ} 11' +$ 

*titude* ...  $27^{\circ} 49'$                       *Height* ... 7051 feet  
*Longitude* ...  $85^{\circ} 17'$                       *Instrument*—T. S. 6-inch Theodolite

*Observer*—Captain H. Wood, R.E.

*Summary.*

No. of pairs 51

No. of observations 93

Mean difference between observations taken E, W and those taken W, E =  $-0''.20$ Observed Co-latitude (weighted mean)  $65^{\circ} 23' 1''.82 \pm 0''.082$ Correction for Height above Sea-level +  $0''.01$ **Final Co-latitude  $65^{\circ} 23' 1''.83$** 

° ' " "

Astronomical Latitude (A) = 24 36 58.17  $\pm 0.082$ 

Geodetic Latitude (G) = 24 36 56.19

Deflection of plumb-line (A-G) = + 1.98

175. Khanpisura 2nd visit\*—Co-latitude  $71^{\circ} 14'$  +

Latitude ...  $18^{\circ} 46'$  Instrument—Zenith Telescope  
Longitude ... 74 49 Mean Height of Barometer  $27^{\circ} 23$  in.  
Height ... 2751 feet Mean Temperature  $65^{\circ} 3$

Observer—Lieut. G. P. Lenox Conyngham, R.E.

*Summary.*

No. of pairs 56

No. of observations 118

Mean difference between observations taken E, W and those taken W, E =  $+ 0''.09$ Observed Co-latitude (weighted mean)  $64^{\circ} 59' 29''.40 \pm 0''.032$ Correction for Height above Sea-level  $0''.00$ **Final Co-latitude  $64^{\circ} 59' 29''.40$** 

---

Astronomical Latitude (A) =  $25^{\circ} 0' 30.60 \pm 0.032$

Geodetic Latitude (G) =  $25^{\circ} 0' 31.53$ Deflection of plumb-line (A-G) =  $- 0.93$

178. Khundabolo—Co-latitude  $70^{\circ} 8' +$ 

Latitude ...  $19^{\circ} 51'$  Instrument—Zenith Telescope  
 Longitude ... 85 1 Mean Height of Barometer  $26^{\circ} 75$  in.  
 Height ... 3115 feet Mean Temperature  $58^{\circ} 8$   
 Observer—Lieut. E. A. Tandy, R.E.

Summary.

No. of pairs 55

No. of observations 110

Mean difference between observations taken E, W and those taken W, E =  $-0''.11$ Observed Co-latitude (weighted mean)  $70^{\circ} 8' 52''.87 \pm 0''.063$ Correction for Height above Sea-level +  $0''.10$ **Final Co-latitude  $70^{\circ} 8' 52''.97$** 

	0	'	"	"
Astronomical Latitude (A)	=	19	51	7.03 $\pm 0.063$

Geodetic Latitude (G)	=	19	51	12.90
-----------------------	---	----	----	-------

Deflection of plumb-line (A-G)	=	-	5.87
--------------------------------	---	---	------

179. Kidarkanta—Co-latitude  $58^{\circ} 59' +$ Latitude ...  $31^{\circ} 1'$ 

Instrument—Zenith Telescope

Longitude ... 78 13

Mean Height of Barometer 18.95 in.

Height ... 12509 feet

Mean Temperature  $27^{\circ}.4$ 

Observer—Lieut. H. M. Cowie, R.E.

*Summary.*

No. of pairs 20

No. of observations 36

Mean difference between observations taken E, W and those taken W, E =  $+ 0''.04$ Observed Co-latitude (weighted mean)  $58^{\circ} 59' 7''.85 \pm 0'' 073$ Correction for Height above Sea-level  $+ 0''.57$ Final Co-latitude  $58^{\circ} 59' 8''.42$ 

	°	'	"	"
Astronomical Latitude (A)	= 31	0	51.58	$\pm 0.073$

Geodetic Latitude (G)	= 31	1	21.71	
-----------------------	------	---	-------	--

Deflection of plumb-line (A - G)	=	-	30.13	
----------------------------------	---	---	-------	--

180. Kistama—Co-latitude  $75^{\circ} 32' +$ 

Latitude ...  $14^{\circ} 27'$  Instrument—Zenith Telescope  
 Longitude ...  $79^{\circ} 48'$  Mean Height of Barometer 29.55 in.  
 Height ... 458 feet Mean Temperature  $69^{\circ} 3'$   
 Observer—Lieut. G. P. Lenox Conyngham, R.E.

Note.—The barometer was read during work every hour, the thermometer every fifteen minutes. For the calculations of refraction a separate value for the pressure and temperature was deduced for each star.

184. Lingmara—Co-latitude  $68^{\circ} 17' +$

Summary.

No. of pairs 47

No. of observations 91

Mean difference between observations taken E, W and those taken W, E =  $0''.00$ Observed Co-latitude (weighted mean)  $66^{\circ} 3' 17''.18 \pm 0''.040$ Correction for Height above Sea-level  $0''.00$ Final Co-latitude  $66^{\circ} 3' 17''.18$ Astronomical Latitude (A) =  $23^{\circ} 56' 42''.82 \pm 0''.040$ Geodetic Latitude (G) =  $23^{\circ} 56' 38''.97$ Deflection of plumb-line (A-G) =  $+ 3''.85$

189. Madras Observatory—Co-latitude  $76^{\circ} 55' +$

Latitude ...  $13^{\circ} 4'$  Maximum recorded Height of Barometer =  $30^{\text{in.}} 17$   
 Longitude ...  $80 17$  Minimum " " " =  $30 \cdot 14$   
 Height ... 54 feet Maximum " Reading of Thermometer =  $78^{\circ} \cdot 8$   
 Instrument—Zenith Sector No. 2 Minimum " " " =  $70 \cdot 0$

Observer—Captain S. G. Burrard, R.E.

Summary.

No. of pairs 53

No. of observations 99

Mean difference between observations taken E, W and those taken W, E =  $+0''.06$ Observed Co-latitude (weighted mean)  $71^{\circ} 22' 11''.93 \pm 0''.055$ Correction for Height above Sea-level +  $0''.13$ Final Co-latitude  $71^{\circ} 22' 12''.06$ Astronomical Latitude (A) =  $18^{\circ} 37' 47''.94 \pm 0''.055$ Geodetic Latitude (G) =  $18^{\circ} 37' 51''.11$ Deflection of plumb-line (A-G) =  $3.17$

194. Mooltan—Co-latitude  $59^{\circ} 49' +$ Latitude ...  $30^{\circ} 11'$ 

Instrument—Zenith Sector No. 1 used as Zenith Telescope

Longitude ... 71 29

Mean Height of Barometer  $29^{\cdot}48$ <sup>in.</sup>

Height ... 420 feet

Mean Temperature  $61^{\circ}0$ 

Observer—Captain S. G. Burrard, R.E.

Summary.

No. of pairs 24

No. of observations 41

Mean difference between observations taken E, W and those taken W, E =  $-0''.11$ Observed Co-latitude (weighted mean)  $67^{\circ} 37' 2''.91 \pm 0''.059$ Correction for Height above Sea-level +  $0''.01$ Final Co-latitude  $67^{\circ} 37' 2''.92$ Astronomical Latitude (A) =  $22^{\circ} 22' 57''.08 \pm 0''.059$ Geodetic Latitude (G) =  $22^{\circ} 22' 56''.38$ Deflection of plumb-line (A-G) = +  $0''.70$

197. Naharmau—Co-latitude  $66^{\circ} 29' +$ Latitude ...  $23^{\circ} 30'$ 

Instrument—Zenith Telescope

Longitude ... 78 52

Mean Height of Barometer  $28^{\circ} 28'$  in.

Height ... 1940 feet

Mean Temperature  $68^{\circ} 0'$ 

Observer—Licut. H. M. Cowie, R.E.

*Summary.*

No. of pairs 22

No. of observations 121

Mean difference between observations taken E, W and those taken W, E =  $- 0''.25$ Observed Co-latitude (weighted mean)  $66^{\circ} 29' 46''.79 \pm 0''.049$ Correction for Height above Sea-level +  $0''.07$ Final Co-latitude  $66^{\circ} 29' 46''.86$ Astronomical Latitude (A) = 23 30 13.14  $\pm 0.049$ 

Geodetic Latitude (G) = 23 30 18.15

Deflection of plumb-line (A-G) = - 5.01

198. Nialamari—Co-latitude  $72^{\circ} 58' +$ 

Latitude	... $17^{\circ} 2'$	Maximum recorded Height of Barometer	= 28 <sup>in.</sup> 950
Longitude	... 79 46	Minimum " " "	= 28 760
Height	... 1144 feet	Maximum " Reading of Thermometer	= $85^{\circ} 0$
Instrument—Zenith Sector No. 2		Minimum " " "	= 72 0

Observer—J. Eccles, M.A.

Note.—The barometer was read during work every hour, the thermometer every fifteen minutes. For the calculations of refraction a separate value for the pressure and temperature was deduced for each star.

*Summary.*

No. of North Stars 35      No. of South Stars 37

No. of observations 211

Co-latitude by North Stars      °   '   "   "

72   58   34.57   ± 0.056

„   „   South   „   72   58   33.50   ± 0.058

Mean Co-latitude   72   58   34.04   ± 0.040

Correction for Height above Sea-level   +   0.03

Final Co-latitude       $72^{\circ} 58' 34'' \cdot 07$

Astronomical Latitude (A)      =   17   1   25.93   ± 0.040

Geodetic Latitude (G)          =   17   1   33.63

Deflection of plumb-line (A—G)   =   —   7.70

199. Nitali—Co-latitude  $71^{\circ} 42' +$ Latitude ...  $18^{\circ} 17'$ 

Instrument—Zenith Telescope

Longitude ...  $76^{\circ} 19'$ 

Mean Height of Barometer 27.73

Height ... 2289 feet

Mean Temperature  $71^{\circ} 0$ 

Observer—Lieut. G. P. Lenox Conyngham, R.E.

Summary.

No. of pairs 61

No. of observations 118

Mean difference between observations taken E, W and those taken W, E =  $+ 0''.07$ Observed Co-latitude (weighted mean)  $71^{\circ} 42' 57''.19 \pm 0''.051$ Correction for Height above Sea-level  $+ 0''.07$ **Final Co-latitude  $71^{\circ} 42' 57''.26$** 

	°	'	"	"
Astronomical Latitude (A)	= 18	17	2.74	$\pm 0.051$

Geodetic Latitude (G)	= 18	17	7.16
-----------------------	------	----	------

Deflection of plumb-line (A-G)	=	-	4.42
--------------------------------	---	---	------

200. Ongole—Co-latitude  $74^{\circ} 30' +$ Latitude ...  $15^{\circ} 30'$ 

Instrument—Zenith Telescope

Longitude ... 80 5

Mean Height of Barometer  $29^{\circ} 70$  in.

Height ... 250 feet

Mean Temperature  $77^{\circ} 1$ 

Observer—Lieut. G. P. Lenox Conyngham, R.E.

## Summary.

No. of pairs 47

No. of observations 167

Mean difference between observations taken E, W and those taken W, E =  $-0''.03$ Observed Co-latitude (weighted mean)  $74^{\circ} 80' 7''.12 \pm 0''.053$ Correction for Height above Sea-level +  $0''.01$ Final Co-latitude  $74^{\circ} 30' 7''.13$ Astronomical Latitude (A) =  $15^{\circ} 29' 52''.87 \pm 0''.053$ Geodetic Latitude (G) =  $15^{\circ} 29' 56''.85$ Deflection of plumb-line (A-G) =  $-3''.98$

201. Oria—Co-latitude  $65^{\circ} 22' +$ Latitude ...  $24^{\circ} 38'$ 

Instrument—Zenith Sector No. 1 used as Zenith Telescope

Longitude ... 72 48

Mean Height of Barometer 25.59

Height ... 4200 feet

Mean Temperature  $68^{\circ} 1$ 

Observer—Captain S. G. Burrard, R.E.

*Summary.*

No. of North Stars 18      No. of South Stars 15  
No. of observations 66

Co-latitude by North Stars      ° ' "      ° ' "      ± 0.063

" " South "      ° ' "      ° ' "      ± 0.070

Mean Co-latitude      ° ' "      ° ' "      ± 0.070

Correction for Height above Sea-level      +      0.17

Corrected Co-latitude by Sector Method      ° ' "      ° ' "      ± 0.047

Corrected Co-latitude by Talcott Method, p. (888)      ° ' "      ° ' "      ± 0.070

**Final Co-latitude       $65^{\circ} 22' 12''.37$**

Astronomical Latitude (A)      =      ° ' "      ° ' "      ± 0.042

Geodetic Latitude (G)      =      ° ' "      ° ' "      ± 0.042

Deflection of plumb-line (A-G)      =      "      "      3.88

202. Parampudi—Co-latitude  $72^{\circ} 47' +$ Latitude ...  $17^{\circ} 18'$ 

Instrument—Zenith Telescope

Longitude ... 81 15

Mean Height of Barometer  $29^{\circ} 20$  in.

Height ... 684 feet

Mean Temperature  $77^{\circ} 0$ 

Observer—Captain G. P. Lenox Conyngham, R.E.

Summary.

No. of pairs 48

No. of observations 89

Mean difference between observations taken E, W and those taken W, E =  $+ 0''.28$ Observed Co-latitude (weighted mean)  $72^{\circ} 7' 1''.59 \pm 0''.068$ Correction for Height above Sea-level +  $0''.09$ **Final Co-latitude  $72^{\circ} 7' 1''.68$** Astronomical Latitude (A) =  $17^{\circ} 52' 58''.32 \pm 0''.068$ Geodetic Latitude (G) =  $17^{\circ} 53' 2''.81$ Deflection of plumb-line (A-G) =  $- 4''.49$

207. Prome—Co-latitude  $71^{\circ} 10' +$ Latitude ...  $18^{\circ} 49'$ 

Instrument—Zenith Telescope

Longitude ...  $95^{\circ} 15'$ Mean Height of Barometer  $29.89$  in.

Height ... 100 feet

Mean Temperature  $71^{\circ}.2$ 

Observer—Captain H. M. Cowie, R.E.

## Summary.

No. of North Stars 44      No. of South Stars 40

No. of observations 174

Co-latitude by North Stars 69 47 8'483 ± 0'016

" " South " 69 47 8'931 ± 0'059

Mean Co-latitude 69 47 8'707 ± 0'037

Correction for Height above Sea-level + 0'04

Final Co-latitude  $69^{\circ} 47' 8'' \cdot 747$ 

Astronomical Latitude (A) = 20 12 51'253 ± 0'037

Geodetic Latitude (G) = 20 12 55'45

Deflection of plumb-line (A-G) = - 4'20

211. Ramai—Co-latitude  $69^{\circ} 3' +$ 

Latitude ...  $20^{\circ} 57'$  Instrument—Zenith Telescope  
 Longitude ... 82 11 Mean Height of Barometer  $28^{\text{in}} 60$   
 Height ... 1313 feet Mean Temperature  $72^{\circ} 4$   
 Observer—Lieut. E. A. Tandy, R.E.

Summary.

No. of pairs 20  
No. of observations 60

Mean difference between observations taken E, W and those taken W, E =  $+ 0''.13$

Observed Co-latitude (weighted mean)  $69^{\circ} 3' 9''.64 \pm 0''.076$

Correction for Height above Sea-level +  $0''.05$

**Final Co-latitude  $69^{\circ} 3' 9''.69$**

Astronomical Latitude (A) =  $20^{\circ} 56' 50.31'' \pm 0.076$

Geodetic Latitude (G) =  $20^{\circ} 56' 51.47''$

Deflection of plumb-line (A - G) =  $- 1.16''$

212. Ramgir—Co-latitude  $71^{\circ} 24' +$ 

Latitude ...  $18^{\circ} 35'$  Maximum recorded Height of Barometer =  $28^{\text{in.}} 176$   
 Longitude ...  $79^{\circ} 34'$  Minimum " " " =  $28^{\circ} 080$   
 Height ... 1772 feet Maximum " Reading of Thermometer =  $82^{\circ} 5$   
 Instrument—Zenith Sector No. 2 Minimum " " " =  $70^{\circ} 5$

Observer—J. Eccles, M. A.

Note.—The barometer was read during work every hour, the thermometer every fifteen minutes. For the calculations of refraction a separate value for the pressure and temperature was deduced for each star.

Summary.

No. of pairs 46

No. of observations 87

Mean difference between observations taken E, W and those taken W, E = + 0".43

Observed Co-latitude (weighted mean)  $71^{\circ} 27' 55''.24 \pm 0''.076$ 

Correction for Height above Sea-level + 0".08

Final Co-latitude  $71^{\circ} 27' 55''.27$ Astronomical Latitude (A) = 18 32 4.73  $\pm 0.076$ 

Geodetic Latitude (G) = 18 32 9.22

Deflection of plumb-line (A-G) = - 4.49

275. Rojhra—Co-latitude  $65^{\circ} 2' +$ Latitude ...  $24^{\circ} 57'$ 

Instrument—Zenith Telescope

Longitude ... 70 17

Mean Height of Barometer  $29^{\cdot}55$ <sup>in</sup>

Height ... 518 feet

Mean Temperature  $63^{\circ}\cdot 8$ 

Observer—Lieut. H. M. Cowie, R.E.

*Summary.*

No. of pairs 64

No. of observations 127

Mean difference between observations taken E, W and those taken W, E =  $+0''.05$ Observed Co-latitude (weighted mean)  $65^{\circ} 2' 33''.89 \pm 0''.032$ Correction for Height above Sea-level  $+ 0''.02$ **Final Co-latitude  $65^{\circ} 2' 33''.91$** 

Astronomical Latitude (A)	=	24	57	26.09	$\pm$	0.032
---------------------------	---	----	----	-------	-------	-------

Geodetic Latitude (G)	=	24	57	26.28
-----------------------	---	----	----	-------

Deflection of plumb-line (A-G)	=	-	0.19
--------------------------------	---	---	------

216. Salimpur—Co-latitude  $62^{\circ} 13' +$ Latitude ...  $27^{\circ} 47'$ 

Instrument—Zenith Sector No. 1 used as Zenith Telescope

Longitude ...  $78^{\circ} 33'$ 

Mean Height of Barometer 29.27

Height ... 645 feet

Mean Temperature  $61^{\circ}.5$ 

Observer—Captain G. P. Lenox Conyngham, R.E.

Summary.

No. of pairs 25

No. of observations 90

Mean difference between observations taken E, W and those taken W, E =  $- 0''.05$ Observed Co-latitude (weighted mean)  $62^{\circ} 13' 23''.74 \pm 0''.050$ Correction for Height above Sea-level +  $0''.03$ **Final Co-latitude  $62^{\circ} 13' 23''.77$** Astronomical Latitude (A) =  $27^{\circ} 46' 36''.23 \pm 0.050$ Geodetic Latitude (G) =  $27^{\circ} 46' 36''.46$ Deflection of plumb-line (A-G) =  $- 0.23$

217. Samdari—Co-latitude  $64^{\circ} 10' +$ Latitude ...  $25^{\circ} 49'$ 

Instrument—Zenith Sector No. 1 used as Zenith Telescope

Longitude ...  $72^{\circ} 37'$ Mean Height of Barometer  $29^{\circ} 55'$ 

Height ... 600 feet

Mean Temperature  $66^{\circ} 0'$ 

Observer—Captain S. G. Burrard, R.E.

## Summary.

No. of pairs 27

No. of observations 121

Mean difference between observations taken E, W and those taken W, E =  $-0''\cdot08$ Observed Co-latitude (weighted mean)  $61^{\circ} 57' 31''\cdot05 \pm 0''\cdot050$ 

Correction for Height above Sea-level + 0'03

Final Co-latitude  $61^{\circ} 57' 31''\cdot08$ Astronomical Latitude (A) = 28 2 28'92  $\pm 0'050$ 

Geodetic Latitude (G) = 28 2 29'00

Deflection of plumb-line (A-G) = - 0'08

220. Sarey Khan—Co-latitude  $67^{\circ} 47' +$ 

Latitude ...  $22^{\circ} 13'$  Maximum recorded Height of Barometer = 29.037 in.  
 Longitude ... 80 5 Minimum " " " = 28.911  
 Height ... 1409 feet Maximum " Reading of Thermometer =  $69^{\circ}.7$   
 Instrument—Zenith Sector No. 2 Minimum " " " = 50.3

Observer—Lieut. S. G. Burrard, R.E.

*Summary.*

No. of North Stars 25      No. of South Stars 27

No. of observations 183

Co-latitude by North Stars      67 47 9.104 ± 0.073

" " South "      67 47 9.484 ± 0.058

Mean Co-latitude      67 47 9.294 ± 0.047

Correction for Height above Sea-level      + 0.05

**Final Co-latitude  $67^{\circ} 47' 9''.344$**

Astronomical Latitude (A)      = 22 12 50.656 ± 0.047

Geodetic Latitude (G)      = 22 12 55.61

Deflection of plumb-line (A - G)      = - 4.95

221. Sarkara—Co-latitude  $60^{\circ} 44' +$ Latitude ...  $29^{\circ} 16'$ 

Instrument—Zenith Sector No. 1 used as Zenith Telescope

Longitude ... 78 85

Mean Height of Barometer  $29.22^{\text{in.}}$ 

Height ... 761 feet

Mean Temperature  $55^{\circ}.9$ 

Observer—Capt. G. P. Lenox Conyngham, R.N.

Summary.

No. of pairs 32

No. of observations 86

Mean difference between observations taken E, W and those taken W, E = + 0".15

Observed Co-latitude (weighted mean)  $61^{\circ} 5' 29''.70 \pm 0''.044$ 

Correction for Height above Sea-level + 0.03

**Final Co-latitude  $61^{\circ} 5' 29''.73$** 

Astronomical Latitude (A)	=	28	54	30.27	$\pm 0.044$
---------------------------	---	----	----	-------	-------------

Geodetic Latitude (G)	=	28	54	39.64	
-----------------------	---	----	----	-------	--

Deflection of plumb-line (A-G)	=	-	9.37		
--------------------------------	---	---	------	--	--

228. Sitapar—Co-latitude  $68^{\circ} 35' +$ 

Latitude ...  $21^{\circ} 25'$  Maximum recorded Height of Barometer = 28.975  
 Longitude ... 80 22 Minimum " " " = 28.781  
 Height ... 1237 feet Maximum " Reading of Thermometer =  $72^{\circ}.5$   
 Instrument—Zenith Sector No. 2 Minimum " " " = 52.8

Observer—Lieut. S. G. Burrard, R.E.

*Summary.*

No. of North Stars 32                      No. of South Stars 33  
 No. of observations 166

Co-latitude by North Stars    68 35 16.225 ± 0.062

"        "        South        "        68 35 16.039 ± 0.069

Mean Co-latitude    68 35 16.132 ± 0.046

Correction for Height above Sea-level                      +    0.04

**Final Co-latitude     $68^{\circ} 35' 16''.172$**

Astronomical Latitude (A)        =    21 24 43.828 ± 0.046

Geodetic Latitude (G)                =    21 24 50.54

Deflection of plumb-line (A - G)        =        -    6.71

229. Sonada—Co-latitude  $66^{\circ} 52' +$ Latitude ...  $23^{\circ} 7'$ 

Instrument—Zenith Sector No. 1 used as Zenith Telescope

Longitude ...  $72^{\circ} 48'$ 

Mean Height of Barometer 29.70

Height ... 250 feet

Mean Temperature  $64^{\circ} 0$ 

Observer—Captain S. G. Burrard, R.E.

Summary.

No. of pairs                    30

No. of observations        77

Mean difference between observations taken E, W and those taken W, E =  $-0''.26$ Observed Co-latitude (weighted mean)  $66^{\circ} 52' 44''.38 \pm 0''.091$ Correction for Height above Sea-level    +     $0''.01$ **Final Co-latitude  $66^{\circ} 52' 44''.39$** 

	°	'	"	"
Astronomical Latitude (A)	= 23	7	15.61	$\pm 0.091$

Geodetic Latitude (G)	= 23	7	19.89
-----------------------	------	---	-------

Deflection of plumb-line (A—G)	=	—	4.28
--------------------------------	---	---	------

230. St. Thomas's Mount—Co-latitude  $76^{\circ} 59' +$ Latitude ...  $13^{\circ} 0'$ 

Instrument—Zenith Telescope

Longitude ...  $80^{\circ} 14'$ Mean Height of Barometer  $29^{\cdot}86$  in.

Height ... 250 feet

Mean Temperature  $72^{\circ}\cdot3$ 

Observer—Lieut. G. P. Lenox Conyngham, R.E.

Summary.

No. of pairs 39

No. of observations 123

Mean difference between observations taken E, W and those taken W, E =  $-0''\cdot31$ Observed Co-latitude (weighted mean)  $76^{\circ} 59' 39''\cdot35 \pm 0''\cdot077$ Correction for Height above Sea-level +  $0''\cdot01$ **Final Co-latitude  $76^{\circ} 59' 39''\cdot36$** Astronomical Latitude (A) = 13 0 20'64  $\pm 0\cdot077$ 

Geodetic Latitude (G) = 13 0 14'79

Deflection of plumb-line (A-G) = + 5'85

237. Surantal—Co-latitude  $65^{\circ} 45' +$ Latitude ...  $24^{\circ} 14'$ 

Instrument—Zenith Sector No. 1 used as Zenith Telescope

Longitude ...  $77^{\circ} 43'$ Mean Height of Barometer  $28.11$  in.

Height ... 1802 feet

Mean Temperature  $59^{\circ}.9$ 

Observer—Captain G. P. Lenox Conyngham, R.E.

Summary.

No. of pairs 54

No. of observations 102

Mean difference between observations taken E, W and those taken W, E =  $0'' \cdot 00$ Observed Co-latitude (weighted mean)  $65^{\circ} 3' 27'' \cdot 34 \pm 0'' \cdot 035$ Correction for Height above Sea-level +  $0'' \cdot 02$ **Final Co-latitude  $65^{\circ} 3' 27'' \cdot 36$** Astronomical Latitude (A) =  $24 \quad 56 \quad 32 \cdot 64 \pm 0 \cdot 035$ Geodetic Latitude (G) =  $24 \quad 56 \quad 36 \cdot 13$ Deflection of plumb-line (A - G) =  $- \quad 3 \cdot 49$

238. Vizagapatam Base-line N. End—Co-latitude  $71^{\circ} 59' +$ Latitude ...  $18^{\circ} 1'$ 

Instrument—Zenith Telescope

Longitude ...  $83^{\circ} 16'$ Mean Height of Barometer  $29^{\text{in.}} 82$ 

Height ... 181 feet

Mean Temperature  $69^{\circ} 0$ 

Observer—Lient. E. A. Tandy, R.E.

*Summary.*

No. of pairs 52

No. of observations 100

Mean difference between observations taken E, W and those taken W, E =  $-0''.10$ Observed Co-latitude (weighted mean)  $71^{\circ} 59' 3''.33 \pm 0''.065$ Correction for Height above Sea-level +  $0''.01$ **Final Co-latitude  $71^{\circ} 59' 3''.34$** 

	°	'	"	"
Astronomical Latitude (A)	= 18	0	56.66	$\pm 0.065$

Geodetic Latitude (G)	= 18	1	2.93	
-----------------------	------	---	------	--

Deflection of plumb-line (A-G)	=	-	6.27	
--------------------------------	---	---	------	--

239. Waltair—Co-latitude  $72^{\circ} 16' +$ Latitude ...  $17^{\circ} 43'$ 

Instrument—Zenith Telescope

Longitude ... 83 22

Mean Height of Barometer  $29^{\circ} 85$  in.

Height ... 200 feet

Mean Temperature  $74^{\circ} 6$ 

Observer—Captain G. P. Lenox Conyngham, R.E.

## ASTRONOMICAL LATITUDES.

---

For the purposes of the next table India has been divided into the ten following regions, which are shown on Plate VI.

1. Himalaya Mountains
2. Plains at the foot of the Himalaya.
3. North-East India.
4. Central India.
5. North-West India.
6. Baluchistan.
7. Western India.
8. Eastern India.
9. Southern India.
10. Burma.

TABLE III.—Deflections of the Plumb-line at Latitude Stations arranged according to Regions.

## Region No. 1.—Himalaya Mountains.

Reference Number		Name of Station	Astronomical Latitude = A	Geodetic Latitude = G	Deflection of Plumb-line = A - G (Northerly negative) (Southerly positive)
From Vol. XI	From pre-sent volume

## APPENDICES.

# APPENDIX.

## No. 1.

### ON DEFLECTIONS OF THE PLUMB-LINE IN INDIA.

BY REV. O. FISHER, M.A., F.G.S.,

*Hon. Fellow of Jesus College, Cambridge, and of King's College, London.*

In the Report of 1901\* on the attraction of the Himalaya Mountains upon the plumb-line in India certain anomalies of deflection are described, which require to be accounted for: and in the Philosophical Magazine for January 1904 I published an article in which I claimed to have shown, that the chief of them may be explained upon the hypothesis of "isostasy" of the earth's crust. The following note is an amended and somewhat abridged edition of that article.

Prefixed to the Report is given a cross-section of outer Himalayan ranges on the meridian of  $77^{\circ} 25'$ , to the scale of one inch to four miles. This was constructed by Colonel St. G. C. Gore, R.E., Surveyor General of India. It appears from this section that through a distance of 124 miles the summits rise fairly regularly from the plains to a height of 18,000 feet. Now according to the maps the ranges in this meridian appear to be inclined at about  $40^{\circ}$  to the prime vertical. Since then the length of the meridian cross-section is 124 miles, that of the section perpendicular to the ranges will be about 95 miles. These outer ranges may therefore, as far as their attraction is concerned, be taken as approximately represented by an inclined plane, or slope, whose base is 95 miles and height 3.3 miles.

Beyond these ranges lies the Tibetan plateau, estimated to be on an average three miles high and 400 miles across. To facilitate calculation I suppose the entire area to be rectangular, and to extend to an equal distance on each side of the meridian of the station. Pratt estimated the area to be equal to that of a circle of radius 335 miles†. This would make the length of the rectangular area about 880 miles. I suppose this mass to have been accumulated out of the compression of a crust 25 miles thick, and that by far the greater volume of the crushed-together mass went down into the denser substratum upon which it is supported by isostasy. I take the density of the crust rock to be 2.68 (that of granite), and that of the substratum to be 2.96 (that of basalt). The consequence of this arrangement would be that for exact isostasy the "root" of the plateau would dip about 29 miles into the substratum, and that the root of the inclined plane of the outer ranges would be represented by an inverted plane having an angle of  $24^{\circ} 31' 5''$ .

Major Burrard has calculated by the method of compartments the deflections which the mountains might be expected to produce at various stations in the meridian of Kaliānpur, and at p. 94 of the Report he has given a table containing an analysis of the calculated deflections, separating the components of the deflection due to the Himalayas from those due to other areas. This affords a criterion as to what extent our assumption respecting the form and position of the visible mass represents for our purpose the actual high land. Major Burrard has assumed 2.65 to be the density, while I have taken 2.68, to agree with the value used in 'Physics of the Earth's Crust,' but the discrepancy is immaterial.

The deflection in the meridian at Dehra Dún due to the mountain masses alone, as calculated by the method of compartments, Major Burrard finds to be 72". Our hypothesis regarding the form and density of the highlands gives 70" as the deflection at the foot of the outer ranges, which is nearly in that position. This shows that the hypothesis reproduces the correct attraction very closely.

There is however reason to doubt whether the "roots" of the slope and plateau would dip into the denser substratum quite so deeply as would be required for exact local isostasy, because Mr. Putnam's 'Transcontinental Gravity Measures, U.S.A.', seemed to show that "general continental elevations are compensated by a deficiency of density in the matter below sea-level, but that local topographical irregularities are not compensated for, but are maintained by the partial rigidity of the earth's crust"‡.

\* By Major S. G. Burrard, R.E., Superintendent of the Trigonometrical Survey of India.

† 'Figure of the Earth,' 4th ed. art. 201.

‡ G. B. Putnam, Phil. Soc. Bulletin, Washington, U.S.A., vol. xii.

Following up the suggestion made by Mr. Putnam we notice how Mr. Oldham tells us that "the very close resemblance between the upper Sivalik beds and the recent deposits of the Gangetic Plain leaves little room for doubt that the Sivalik beds were deposited subaerially by streams and rivers." "The thickness attained by the Sivalik series is immense. Mr. Wynne estimated it at 14,000 feet in the North-West Punjab. In the Sivalik Hills there are at least 15,000 feet of beds and the series is by no means complete, and similar vast thicknesses may be measured in any section." In Mr. Oldham's diagram (Man. Geol. India, p. 473) (fig. 1) he represents the Sivalik strata as lying beneath modern alluvium except at the northern edge where they have been disturbed and elevated into the Sub-Himalayan Sivalik range. Following the above description, we may assume a layer of rock of somewhat less than crust density three miles thick where it abuts on the foot of the Himalayan slope, and thinning out to nothing against the trappean area. It will be observed that a

Fig. I

"Diagram to illustrate the theory of the elevation of the Himalayas corresponding to the right-hand half of fig. 26 (copied from 'Physics of the Earth's Crust'). Horizontal scale about 60 miles; vertical about 30 miles to one inch. [This makes the crust much thinner than assumed in P.E.C.]

- A. Massif of the Himalayas.
- B. Root of the same.
- C. Earlier marginal deposits compressed and elevated.
- c. Continuation of the same, depressed and undisturbed.
- D. Subsequent deposits overlapping C.
- b. Sinking of lower surface of crust due to C and D.\*

pile of rock three miles thick above the surface of the sphere would reach an altitude equal to that of the Tibetan plateau, but the Gangetic plains do not rise to as much as a thousand feet above the sea-level, and the recent alluvium has to be allowed for. The conclusion is that the crust of the earth must be depressed 15,000 feet at least into the substratum at the foot of the Himalayan slope. We need, therefore, to calculate the effect of this arrangement upon the plumb-line.

According to the present hypothesis, the Himalayas and Tibetan plateau are not supported solely by the root immediately beneath them, but partly by the depressed crust beneath the Sivalik rock of the plains. It follows that for isostasy the root of the plateau and slope will not need to be quite so deep; we may take the height of the plains above the sea-level as compensating their presumable defect of density from that of the general crust.

The width of the alluvium, where the meridian of Dehra Dún in Mr. Oldham's geological map crosses its boundary, appears to be about 230 miles. This will give for the base of the Sivalik beds an inverted inclined plane, whose depth is three miles and width 230. If we apply the principle of *general* isostasy to half of the area we are dealing with, that is,

Fig. 2.

Modification of Mr. Oldham's diagram to suit the present hypothesis.

Scale about 105 miles to an inch.

- A. Slope of the Himalayas, including the marginal deposit C of Mr. Oldham's diagram.
- B. Root of the same.
- D. Sivaliks undisturbed and covered by subsequent deposits.
- b. Sunken lower surface of the crust contributing to the general support of half the highlands according to Mr. Putnam's theory.

from the middle of the Tibetan plateau to the further edge of the alluvial deposit 230 miles from the foot of the slope, we find that the depth of the root of the plateau will be diminished by one mile and four tenths, or more exactly the depth of the root of the plateau for exact isostasy would be 28·71 miles, and the diminution for general isostasy 1·39 miles, which gives for the depth of the root of the plateau 27·32 miles, and for that of the slope at its culminating height 30·19 miles. By this change the attractions of the visible masses and of the crust will not be altered, but the negative attraction of the root will be slightly diminished, and the balance of attraction towards the range consequently increased.

Looked at in a general way, the visible masses of the highlands will attract the plumb-line towards them, their roots, where the denser substratum is displaced by the lighter crust, will repel the plumb-line, and the deflection at any station will be the balance of the two effects.

The effect of the plain will resemble that of the mountains' roots, because it will depress and displace the heavier substratum. Consequently at either edge the plain will produce a deflection away from itself, northward at the northern edge and southward at the southern, while at some intermediate place the effect of the plain will be *nil*.

To estimate the final deflection at any station we must strike the balance of all these effects.

It must be borne in mind that the object of this investigation is one of principle, and that no exact accordance with the results of the Survey is to be expected, because the natural data cannot be presented in a form amenable to mathematical treatment.

The following is a summary of the results of the hypothesis:—

At the foot of the slope the meridional deflection will be,

Due to the slope	...	...	...	30"·210
Due to the plateau	...	...	...	40 ·014
Total due to the visible masses	...	...	...	70 ·254
Negative deflection due to the root	...	...	...	51 ·825
Residual deflection, northward	...	...	...	18 ·429
Northward negative deflection due to the plain	...	...	...	3 ·837
Final result, northward	...	...	...	22 ·266

At 60 miles from the foot of the slope the meridian deflection will be,

Due to the slope	...	...	...	11"·804
Due to the plateau	...	...	...	28 ·924
Total due to the visible masses	...	...	...	40 ·728
Negative deflection due to the root	...	...	...	37 ·156
Residual deflection, northward	...	...	...	3 ·572
Southward deflection due to the plain	...	...	...	1 ·049
Final result, northward	...	...	...	2 ·523

The meridian deflection at the southern edge of the plain will be,

Due to the slope	...	...	...	3"·884
Due to the plateau	...	...	...	14 ·923
Total due to the visible masses	...	...	...	18 ·807
Negative deflection due to the root	...	...	...	17 ·333
Residual deflection, northward	...	...	...	1 ·474
Southward deflection due to the plain	...	...	...	3 ·006
Final result, southward	...	...	...	1 ·532

Thus the hypothesis of the general isostasy of the Himalayan region and the Gangetic plain combined gives the considerable meridian deflection of 22" northward at the foot of the range. At a distance of 60 miles from the foot of the slope this deflection will be reduced to about 2".5, and at a greater distance disappears altogether. These results are in accordance with Airy's prediction.\* The deflection then changes its sign, and becomes southerly, and is 1".5 in the meridian at the further edge of the plain. At a greater distance the effect of the plain would no doubt disappear, which would account for the deflection at the edge of the plain being more southerly than it is at Kaliánpur.

It is owing to the thickness of the crust that the attraction of the visible masses, though nearly compensated by the root at a distance from them, is much less so at places in their neighbourhood.

The extreme difference of the deflections in the meridian at the northern and southern edges of the plain will thus be about 24". In the table following p. 14 of the Report it is, in the meridian of Kaliánpur, about 30", as observed†.

It is obvious that the dense rock of the Deccan will tend to intensify the southerly deflection on the southern edge of the plain, and that, in general, irregularities in the geological structure of the country buried beneath the post-cocene deposits will be responded to by irregularities in the deflection of the plumb-line. That this must occur appears from the table, where, in the column of deflections, there are irregularities over the plain which seem inexplicable in any other way.

Nevertheless, on the whole the trend of the deflections from the foot of the slope to the southern edge of the plain in the meridian of Kaliánpur has been fairly well accounted for; and the existence of an area of southerly deflections, as indicated in the table following p. 14 of the Report, explained, without the necessity of assuming the presence of a chain of excessive density, seeing that it would be the natural consequence of the displacement of the dense substratum by the depression of the Gangetic plain in accordance with the general isostasy of the entire region.

Moreover, the hypothesis of general rather than local isostasy permits us to suppose that the root of the southern portion of the Himalayas is somewhat less deep, and that of the Tibetan plateau deeper than would be required for local isostasy, and the geological observation that compressive elevation is going on along the main axis† appears to support this view. If this be the case, the repulsive effect of the root would be diminished at the foot of the slope, on account of the greater distance of the mean mass of the root; and the deflection caused by the visible masses would be less nearly compensated. This would bring the excess of deflection at the foot of the slope above that at the southern edge of the plain more into accordance with the observed amount.

It must be remembered that certain gratuitous hypotheses have been made, which will affect the quantitative, though not the qualitative, results of this investigation. Such are the relative densities of the crust and substratum and the thickness of the crust. But the quantitative agreement of the results with the observed facts shows that the assumptions made are not very improbable.

\* Phil. Trans. vol. cxlv. p. 102.

† The following is taken from the above table. N signifying a northern and S a southern deflection as referred to Kaliánpur:—

"Ever since our great pioneer in Himalayan geology, Mr. Medlicott, first examined and described the Sub-Himalaya in his memoir (Mem. Geol. Surv. of India, vol. iii.) and since the Rev. O. Fisher wrote his far-seeing 'Physics of the Earth's Crust,' it has been gradually becoming evident to all who really examine the question in detail, that the Himalayas are and have been in a constant state of change: a state of elevation along the main axis and depression along the mountain foot, with intermediate zones of crushing, crumpling, and over-riding along shear and thrust planes. This is so evident that, if one desired to be very particular, one might say literally that the Himalayas of to-day are not the same as those of yesterday."—Memoirs of the Geological Survey of India, vol. xxvi. by C. S. Middlemiss, p. 285.

## MATHEMATICAL NOTES.

## I.—Attraction of the Mountains.

The diagram (fig. 3) represents a section perpendicular to the range. It is drawn approximately on a scale of  $\frac{1}{10}$  of an inch to 5 miles. K M C F B is the crust, out of which the mountains and their roots were formed, and is supposed

Fig 3

to be 25 miles thick. G H D K is the Tibetan plateau, three miles high and 400 miles across. D A H is the slope of the mountains, A D being 95 miles. D H is 3.3 miles. M L K E is the root of the plateau. E R equals 28.71 miles. E R C is the root of the slope.

We require to find the horizontal attraction at a station P on the surface of the crust. P may be either to the right or left of B. Sphericity is neglected. Then the horizontal attraction of the mountain and root together at P equals the horizontal attraction, positive of the slope, *plus* that of the plateau, combined with the horizontal attraction, negative produced by the substitution of their less dense roots for the more dense substratum. The crust, whether disturbed or not, will produce no horizontal attraction. The negative attraction of the root will be the same in amount as if the root was composed of matter whose density was equal to the excess of the density of the substratum over that of the crust, and the attraction of the root M L R C at P will be the same as would be produced by a mass K L R C B *minus* that which would be produced by a mass K M C B, each mass being of similar density. Consequently we need to calculate these several attractions. The attraction having been calculated from the formulæ, the corresponding deflection may be found by multiplying it by a factor whose logarithm is 0.3541084\*.

$$\begin{aligned} \text{Attraction of the slope} \Big\} = 2\rho \Big\{ (a \pm p \cos^2 a) \tan^{-1} \left( \frac{a}{a \pm p} \tan a \right) \mp \frac{p}{2} \sin a \cos a \log \left( 1 + \frac{a(a \pm 2p \cos^2 a)}{p^2 \cos^2 a} \right) \right. \\ \left. - \frac{ha}{2l^2} \left( \frac{a}{3} \pm \frac{p}{2} \right) \right\}. \end{aligned}$$

The upper or lower sign is to be used according as the attracted particle P is to the right or left of the foot of the slope under consideration.

$$\text{Attraction of the plateau} = 2\rho \left\{ x \tan^{-1} \frac{lh}{xv} - \frac{h}{2} \log_e \frac{v+l}{v-l} - \frac{l}{2} \log_e \frac{v+h}{v-h} \right\} + \text{const.}$$

The limits of  $x$  are the nearest and furthest distances of the base of the plateau from the station P, *viz.*, PD and PD + 400.

$$v = \sqrt{l^2 + h^2 + x^2} \text{ and its limits depend upon those of } x.$$

The unit of length is a mile.

2l is the length of the range = 880.

(1) When the attraction of the slope HDA is required:

$$\rho = 2.68.$$

$$a = DA = 95 \text{ miles} \dagger.$$

$$h = 3.3 \text{ miles.}$$

$$\tan a = \frac{HD}{DA} = \frac{h}{a} = \frac{3.3}{95}.$$

$$l = 440.$$

$p$  is the distance from the foot of the slope A of the station where the attraction is required

\* See Clarke's 'Geodesy,' p. 296

† Observe: In the Addendum DA is taken at 95 miles.

- (2) When the attraction of DRB is required :

$$DE = 25.$$

$$\rho = 2.96 - 2.68 = 0.28.$$

$$h = ER = 30.191.$$

$$\tan \alpha = \tan \angle ECR = \frac{ER}{DA} = \frac{30.191}{95}.$$

$$a = AD + AB = 95 + DE \cot \alpha = 173.666.$$

$p$  is the distance from B of the station.

- (3) When the attraction of ACB is required :

$$\rho = 0.28.$$

$$\tan \alpha = \frac{30.191}{95}.$$

$$a = 25 \cot \alpha = 78.666.$$

$$h = 25.$$

$p$  is the distance from B of the station.

## II.—Attraction of the Plain.

Referring to figure 2,

Let  $a$  be the width of the plain  $DR = 230$  miles.

$k$  the thickness of the crust = 25 miles.

$p$  the distance from the southern edge of the plain of a station P where the deflection is required.

$\rho$  the difference of the densities of the crust and the substratum = 0.28.

$m$  the tangent of the angle at which the under side of the crust is depressed into the substratum =  $\frac{3}{230}$ .

$l$  the length of the area supposed rectangular, and conterminous with the mountain range.

Then the attraction of the plain at P may be found from the following formula, it being premised that the attraction so obtained will be a negative attraction, due to the displacement of the dense substratum by the lighter crust thrust down into it. Consequently negative results will indicate deflections towards R, the southern edge of the plain, and positive ones deflections towards C, the foot of the slope of the Himalayas.

$$\begin{aligned} \text{Attraction of the plain} = & 2\rho \left\{ a \tan^{-1} \frac{ma(a-p)}{(a-p)^2 + k(k+ma)} - \frac{mk-p}{1+m^2} \tan^{-1} \frac{a(mp+k)}{(p^2+k^2) + (mk-p)a} \right. \\ & \left. - p \frac{ak}{k^2 - p(a-p)} + \frac{mp+k}{1+m^2} \frac{1}{2} \log_e \left( \frac{a(a(1+m^2) + 2(mk-p))}{p^2+k^2} + 1 \right) - \frac{k}{2} \log_e \frac{(a-p)^2 + k^2}{p^2+k^2} - \frac{ma^2}{2l^2} \left( \frac{a}{3} - \frac{p}{2} \right) \right\} \end{aligned}$$

If we put  $\tan \alpha = \frac{h}{a}$ , the expression for the attraction of the slope may be put into the form

$$2\rho \left\{ a \frac{a^2 + h^2 \pm ap}{a^2 + h^2} \tan^{-1} \frac{h}{a \pm p} \mp \frac{p}{2} \frac{ah}{a^2 + h^2} \log_e \frac{(a \pm p)^2 + h^2}{p^2} - \frac{ha}{2l^2} \left( \frac{a}{3} \pm \frac{p}{2} \right) \right\};$$

which is slightly more convenient for computation. In the expression for the attraction of the plateau, when  $x$  is considerably larger than  $h$ , the sum of the first and third terms, viz.,  $x \tan^{-1} \frac{lh}{xv} - \frac{l}{2} \log_e \frac{v+h}{v-h}$ , may be taken as approximately equal to

$$-\frac{l}{3} \left( \frac{h}{v} \right)^3 \frac{(v+h)(v-h)}{x^2}.$$

In the case of the visible masses this sum is inappreciably small.

The attraction of the plain might also be found in a manner similar to that used for ECR, by taking a difference of two attractions.

# APPENDIX.

## No. 2.

### DETERMINATION OF THE GEODETIC ELEMENTS OF THE LATITUDE STATIONS OF BAJAMARA, BAHAK, LAMBATACH AND KIDARKANTA.

#### 1.

##### *General Remarks.*

The triangulation emanated from the side Banog-Sirkanda of the Principal Triangulation of the Great Trigonometrical Survey: the station of Nag Tiba was fixed in October 1902 by Captain Wood, R.E., observing with Troughton and Simms' 12-inch theodolite on 12 zeros.

In order to determine the geodetic elements of the Latitude Stations, Captain Cowie, R.E., observed the angles of two single triangles and one quadrilateral on 12 zeros with Troughton and Simms' 7-inch theodolite in October, November and December 1903, *vide* Triangulation chart attached.

#### 2.

##### *Descriptions of Stations.*

**BANOG HILL STATION** is a principal station of the Great Arc Meridional Series, Section 24° to 30° and is situated on a detached peak of the lower range of the Himalaya Mountains, being thrown back about a mile to the north of the range whereon stands the sanitarium of Mussooree. The station is in the district of Dehra Dún.

The pillar is solid, and 2 feet high. It has a mark-stone at top, and another at bottom.

**SIRKANDA HILL STATION (NEW)** is a principal station of the Great Arc Meridional Series, Section 24° to 30°. It was made to coincide as nearly with the site of the old station of that name, described in Synoptical Volume II, as could be estimated from the remains of the platform found there, the isolated pillar together with the mark-stones having been removed by Natives visiting the temple to build a wall round it. The present mark is distant from the N.W. corner of the temple 26 feet 6 inches, from the S.W. corner 18 feet 7 inches, and from the S.E. corner 31 feet 2 inches.

The pillar is solid and two feet high, having a mark-stone embedded level with the surface, and is surrounded by a platform from which it is isolated. In 1902-03, the station was found to consist of an unisolated pillar of stones and mud. This was carefully pulled down and a small mark-stone was found at the bottom of the pillar close to a large rock *in situ*. This mark-stone was not disturbed, but the ground on one side of it was excavated 2 feet lower down, but no other stones or remains of a pillar were found. This forms the lowest mark-stone of the new pillar.

A new pillar has been built of which the mark-stones are all vertically above that found *in situ* and which forms the lower mark-stone of the new pillar. This is circular in shape, 40 inches in diameter and 3 feet  $\frac{1}{4}$  inch high, built of rubble masonry, in lime, and isolated by an annulus 2 feet thick at the bottom and 1 foot at the top, and of similar height to the pillar, leaving a concentric space, 3 inches wide around the pillar. The lower and centre mark-stones are 3 feet 0.25 inch and 1 foot 6.5 inches respectively below the upper one. Around the annulus a platform of earth and stones 14 feet square has been built.

**NAG TIBA HILL STATION** is situated on the summit of the highest of three peaks known locally by that name on the watershed of the Bhágirathi and Jumna rivers, about 3 $\frac{1}{4}$  miles N.N.W. of Unthal village on a branch of the Uglar, a confluent of the latter, and 2 $\frac{3}{4}$  miles E. of Parbati on the Badri (Tehri-Garhwál). The hill can be approached from Mussooree in two marches by several different paths all of which are very steep in places. There is a site for a good camping ground on the spur running north from the station and water is found on the north side of the main ridge to the east.

A circle and dot inscribed on the upper surface of a stone embedded centrally in a circular masonry pillar 40 inches in diameter and 2 feet high. Vertically below this upper mark two other stones similarly inscribed are embedded at the centre and in the foundation of the pillar respectively. Around the pillar a circular masonry ring has been built, 1 foot thick, and of similar height as the pillar, leaving a concentric space 3 inches wide and surrounding this a platform of earth and stones 14 feet square has been constructed.

**BAJAMARA HILL STATION** is on the top of the peak locally known as Bajamara, on the watershed between the Tons and Jumna valleys. The station is not identical with Bájámárá h.s. of Synoptical Vol. VII, which is 170 feet lower and about a mile to the west. A cairn of stones and a pole, possibly triangulation signal, was found on the top, but no such mark was found on the top of the lower peak.

It is marked in the usual way by a circle and dot on a large stone found about 1 foot below the surface of the ground. Over this is built a circular masonry pillar  $1\frac{1}{2}$  feet high and 3 feet in diameter, carrying at its centre, on the upper surface, a second similar mark vertically over the lower. It lies in the lands of the village Khatt Kailana, District Dehra Dún, and is about 100 yards from the Chakráta-Mandali road which runs round the southern and eastern faces of the hill. The station is 2 miles from Deoban F. B. and  $3\frac{1}{2}$  miles from Mandali F.B. There is no good camping ground near the station, and good water is to be found only at a considerable distance.

The latitude station is 12 feet  $6\frac{1}{2}$  inches north and 46 feet 10 inches west of the trigonometrical station.

**BAHAK HILL STATION** is on the highest point of the hill of the same name in the lands of the village Kaprole, Patti Mungar Santi (Tehri-Garhwál) on the watershed of the Bhágirathi and Jumna rivers, about  $2\frac{1}{4}$  miles E. N. E. of Tehliank village on the Burni stream entering the latter, and  $5\frac{1}{2}$  miles N. W. of Gula village on stream entering the former between Gula and Thara villages.

The point is marked by the usual circle and dot inscribed on a stone. Over this lower mark is built a circular masonry pillar 2 feet 5 inches high and 3 feet in diameter carrying at the centre of its upper surface an upper mark vertically above the lower. Surrounding this pillar but isolated from it is a masonry platform 14 feet square and built to a level 3 inches higher than the top of the pillar.

The station is easily approached from the south from Chajoola village or from the west from Kaprole. There is a site for a small camp, a short distance west of and below the station, but the nearest good water is over 2 miles in the same direction.

The latitude station is 5 feet 11 inches south and 24 feet  $3\frac{1}{2}$  inches east of the trigonometrical station.

**LAMBATCH HILL STATION** is on the highest point of Lambatach hill, which lies N.E. from the junction of the Pabar and Tons Rivers, in the lands of village Manjni, Patti Pingal (Tehri-Garhwál), about  $1\frac{3}{4}$  miles N.W. of Deota F.B., 1 mile N.E. of Maijon and Lambatach F.B.

The circle and dot are cut in a stone embedded in the upper surface of a masonry pillar 3 feet in diameter and one foot high. This mark is placed vertically over the mark defining Lambatach or Lambáthásh of the Secondary Triangulation (*vide* Synoptical Vol. VII). The pillar is isolated in the usual manner from the surrounding platform.

The easiest approach is *via* Thadiar and Deota F.B.

The Latitude Station is 82 feet  $1\frac{1}{2}$  inches north and 1 foot  $8\frac{1}{2}$  inches east of the trigonometrical station.

[There may be a slight local deflection of the plumb-line southwards, less than  $1''$  in amount probably. H.M.C.]

**KIDARKANTA HILL STATION** is on the highest point of Kidarkanta hill on the watershed between the Tons and Jumna valleys in the lands of village Durgaon, Patti Siktur (Tehri-Garhwál), and is about  $\frac{1}{4}$  mile E. of the higher road from Onot and Balshul villages to Shauro by Our village, about  $3\frac{1}{4}$  miles N. N. E. of Our,  $3\frac{3}{4}$  miles E. of Lodráo and  $3\frac{1}{2}$  miles S. a little W. of Shauro village.

The point is marked by a circle and dot cut on the upper surface of a stone embedded centrally in a circular masonry pillar 3 feet in diameter and 2 feet high. Vertically below the upper mark, a lower similar mark is embedded below the pillar. The pillar is isolated in the usual manner from the surrounding platform which is built up to the level of the upper surface of pillar.

The station is most easily approached from the north, the best route being Chakráta, Mandali, Thadiar, Sendra F.B., Naintwar F.B. (By Gainchra village) and Kidarkanta.

The Latitude station is 38 feet south and 32 feet east of the trigonometrical station.

[The station seems well placed as regards the mass of the hill itself, and no local disturbance of the plumb-line of any size need be expected. There is a small preponderance of mass to the south. H.M.C.]

## No. 3.

### ON THE (N-S) DIFFERENCE EXHIBITED

BY

#### ZENITH SECTOR NO. 1.

*Extracted from the report of Captain Burrard for the Season 1892-93.*

The instrument used this season was zenith sector No. 1. It was designed by Colonel Strange, and purchased by the Indian Government in 1871. It is a sister instrument to zenith sector No. 2, but is in many ways superior to the latter. Zenith sector No. 2 arrived in India in 1870, and was used by Colonel Herschel in 1870-71. Colonel Herschel suggested many valuable improvements and additions, which the makers had time to adopt in the construction of zenith sector No. 1.

Zenith sector No. 2 has been used on several occasions in the last twenty years, and has always given uniformly good results. On the other hand, zenith sector No. 1 was only used once, and that occasion was in 1871-72, when Colonel Campbell observed for latitude at eight stations of the Mangalore Meridional Series. At those eight stations the zenith sector exhibited a “(N-S) difference,” by which is meant that a difference was found to exist between the results by north and south stars respectively; the latitude derived from observations by north stars was always given too small, whilst the latitude derived from south stars was always given too large.

Now for north stars—

$$\text{Latitude} = \text{declination} - \text{zenith distance},$$

and for south stars—

$$\text{Latitude} = \text{declination} + \text{zenith distance}.$$

It thus became apparent that this instrument, zenith sector No. 1, measured *all* zenith distances too large. Colonel Campbell writes in 1872: “Zenith sector No. 1 measures zenith distances in excess of their true value, and the most superficial examination shows that the error is a function of the zenith distance, being nearly exactly in direct proportion to it.” In fact this (N-S) difference was apparently subject to a law: every zenith distance was observed too large, the error in a Z.D. of  $10^\circ$  being twice the error in a Z.D. of  $5^\circ$  and ten times the error in a Z.D. of  $1^\circ$ . On account of this (N-S) difference, zenith sector No. 1 has been laid aside for twenty-two years and never used since its first season.

In 1890 a zenith telescope arrived in India, and the method of observing astronomical latitudes was changed from the “sector” method to the “Talcott” method. By the sector method the absolute Z.D. of a star is observed, and the latitude deduced from the formula—

$$\text{Latitude} = \text{declination} \pm \text{zenith distance}.$$

By the Talcott method the *difference* of Z.D. is observed between a north and south star, and no absolute zenith distance is measured. Thus a pair of stars are chosen, one north and one south, that transit within a few minutes of each other, and that are as nearly as possible the same distance from the zenith. The telescope is set to the mean Z.D. of the pair, and pointed to whichever star of the pair transits first. The star is intersected by the micrometer. The telescope is then revolved on its vertical axis  $180^\circ$  in azimuth, but its setting is not disturbed. It will now be pointing to the second star of the pair: this star is also intersected by the micrometer. The difference of the micrometer readings is equal to the *difference* between the zenith distances of the two stars, and this quantity is all that we have to measure. If  $d_n, d_s$  = declinations of the two stars, and  $z_n, z_s$  their zenith distances, then the Talcott formula is—

$$\text{Latitude} = \frac{d_n + d_s}{2} - \frac{z_n - z_s}{2}.$$

We measure  $(z_n - z_s)$ , but do not require the absolute values of  $z_n$  and  $z_s$ .

The zenith telescope gave excellent results, and was consequently looked upon as a good instrument. But it became evident that zenith sector No. 1 would also have given excellent results, with no (N—S) difference, if it had been worked as a zenith telescope by the Talcott method.

In the formula—

$$\text{Latitude} = \frac{d_n + d_s}{2} - \frac{z_n - z_s}{2},$$

$z_n$  and  $z_s$  would have been observed both too large, but  $z_n$  and  $z_s$  being nearly equal, the errors in their measurements would also have been equal, and their difference ( $z_n - z_s$ ) would have remained correct, for the peculiarity of the (N—S) difference was, that errors in equal zenith distances were equal. The state of the case was this then: zenith sector No. 1, a very valuable instrument, was lying discarded, because it showed a (N—S) difference with the sector method, though it clearly would have given excellent results if used with the Talcott method. On the other hand, the new zenith telescope was being constantly used, merely because it gave good results with the Talcott method, though it had never been tried with the sector method: for anything known to the contrary, this new zenith telescope might also exhibit a (N—S) difference, if worked with the sector method. For these reasons I obtained sanction from the Deputy Surveyor-General to be allowed to use the zenith sector No. 1 this season on the Jodhpore Meridional Series, and to work it both on the Talcott and sector method.

After a season's experience with this zenith sector, I am of opinion that the (N—S) difference is due to a constant error running throughout the graduation of the limb, and that it in no wise vitiates results.

This season, 1892-93, the same (N—S) difference to the last decimal place has appeared, as was discovered by Colonel Campbell in 1871. As flexure of the telescope tube has at times been suggested as the cause of the phenomenon, I should like to give my reasons for thinking that flexure has nothing to do with it.

The image of a star is seen on the centre wire, when the line joining the star with the centre wire passes through the centre of the object glass. If then the instrument be perfectly adjusted, and the telescope be set at an angle  $\theta$  with the vertical, a star of zenith distance  $\theta$  will be observed on the centre wire, provided the telescopic tube does not suffer from flexure. If however there is flexure of the object end, the object glass will be lower than in its correct position, and the line joining it with the centre wire will make a larger angle than  $\theta$  with the vertical, though the angle of inclination, as read on the limb, remains unchanged at  $\theta$ . If instead of the object end it is the eye-end that is suffering from flexure, the centre wire will fall lower than its correct position, and the line joining the centre wire with the centre of the object glass will consequently make an angle *less* than  $\theta$ , the reading of the limb still remaining  $\theta$ .

Therefore, if the telescope be permanently set at angle of  $\theta$  with the vertical, the following cases occur: (i) If there is no flexure, the image of stars of zenith distance  $\theta$  will appear on the centre wire; (ii) if there is flexure of the object end, the image of stars of a zenith distance somewhat *greater* than  $\theta$  will appear on the centre wire; and (iii) if there is flexure of the eye-end, the image of stars of a zenith distance somewhat *less* than  $\theta$  will appear on the centre wire. In other words, if there is flexure of the object end, the observed zenith distance will be *less* than the true zenith distance, whilst if there is flexure of the eye-end, the observed zenith distance will be *greater* than the true zenith distance. Now, in the zenith sector No. 1, the instrument under review, observed zenith distances are always too large, and hence if flexure be the cause of this phenomenon, it must be flexure of the eye-end.

The following considerations led me to abandon the theory of flexure and to seek another cause:—

- (a) The telescope tube is elliptical in cross-section, and especially designed against flexure.
- (b) The object end is longer than the eye-end, and is consequently more liable to flexure than the eye-end, but if the (N—S) difference be due to flexure, it must be flexure of the eye-end.
- (c) As pointed out by Colonel Campbell, the (N—S) difference is clearly subject to a law, and varies accurately with the amount of the zenith distance. I cannot conceive a telescope, that waves from side to side after the manner of a fishing-rod, obeying any such law. The amount of flexure would not only depend on the zenith distance, but on the direction of motion, with which the telescope was brought up into position, and on the rapidity of this motion.
- (d) After lying in its box, discarded as useless for twenty-two years, it is tried again, and in 1893 the (N—S) difference in its ratio to the zenith distance is precisely the same as it was in 1871. Can the bending properties of any metal act so accurately, and remain so constant?

Now, in one of the astronomical circles there was also a large (N—S) difference, but in this instrument zenith distances were measured in *defect* of the truth, as would be the case if there were flexure of the object end: moreover the amount of the error was subject to no traceable law whatever, and it was but reasonable to attribute the (N—S) difference to flexure.

I believe now that the (N—S) difference in zenith sector No. 1 is due to error of limb graduation. Zenith distances are all measured too large, and this is exactly what would occur *if the graduations of the limb of the vertical circle were all too small for the radius of the limb*. The amount of the (N—S) difference is such that an angle of  $10^\circ$  is measured on the vertical circle as  $10^\circ 0' 1''.80$ . The effect on resulting values of latitude may be found thus: suppose a north star and a south star are both observed for latitude, both having a zenith distance of  $10^\circ$ . In both cases their zenith distance, as observed, will be  $10^\circ 0' 1''.80$ .

In the case of the north star: latitude = declination — Z D.; and the resulting latitude will be  $1''.80$  too small. In the case of the south star: latitude = declination + Z.D.; and resulting latitude will be  $1''.80$  too large.

The two values of latitude by the two stars will thus differ by  $3''.60$ : in the ordinary astronomical latitudes, as observed in India, it is quite common for results from forty stars (each observed four times) to all fall within a range of two seconds of arc, and differences of  $3''.6$  are quite inadmissible: if moreover the two stars in the above example had each had a Z.D. of  $15^\circ$  instead of  $10^\circ$ , the difference between their resulting values of latitude would be  $5''.4$ .

Now, the limb of the zenith sector is not a complete vertical circle, but consists of two segments of  $50^\circ$  each, struck, or intended to have been struck, with a radius of 18 inches.

The surface of the limb is, moreover, not in the plane of the circle of the limb: the sectors are "dished," and meet at an angle at their junction at the horizontal axis: the silver limb has been let into a groove cut on the face of the brass sectors: the surface of the limb is such that if it were produced inwards, it would form not a circle but a cone with its apex at the horizontal axis. It seems apparent that the artificers' difficulties in centering and graduating such segmental arcs, and in placing them in their proper positions relatively to one another, must be greater than in the case of a theodolite with a complete plane horizontal circle. Yet in many of our best theodolites periodic errors amounting to  $1''.8$  in  $10^\circ$  have been found.

Now, suppose the graduations of the two arcs of  $55^\circ$  have all been made at too small intervals from one another, and that on each arc the graduations for the whole  $55^\circ$  have been distributed through an angular space of only  $54^\circ 59' 50''.1$ . In the zenith sector this error cannot be compensated, as the limb is not complete: in the horizontal circle of a theodolite it would be compensated. In this latter case, the whole circle must be eventually divided into 360 degrees, so that if the graduations are placed too near together at one part of the limb, they must be too far apart at another, and if the well-known method of changing zero be followed, angles measured with such a circle are unaffected by these periodic errors.

But with the zenith sector there is not only no means of changing zero, but the compensating portion of the limb is altogether absent: so that if there is any error in limb graduation, whether periodic or not, it cannot be got rid of.

Supposing the (N—S) difference to be due to graduation error, the amount of the artificer's error may be arrived at thus: the radius of the limb should have been 18 inches, so that the length of an arc of  $10^\circ$  measured along the limb *should* be 3.1416 inches: but by observation we have found that an angle of  $10^\circ$  at the centre is subtended at the limb by graduations of  $10^\circ 0' 1''.8$ . This can have resulted in two ways: either the limb has been graduated with a radius of 17.9991 inches and then placed on the sectors with a radius of 18 inches, or else the graduations must have been made with a correct radius of 18 inches, but the limb through some miscalculation was shrunk on to the sectors with a radius of 18.0009 inches. One fact is clear, *viz.*, that the radius of the limb is 0.0009 inch too large for its graduations.

Suppose the two arcs of  $55^\circ$  are each produced circularly into arcs of  $180^\circ$ , the graduations being made at the same intervals as at present. Then, when the graduations have been extended to  $180^\circ$ , each arc of  $180^\circ$  will only subtend at the centre an angle of  $179^\circ 59' 27''.6$ . At each of the two points of junction the final graduations instead of being coincident, as they ought to be, will be apart by 0.00282744 of an inch, the length on the limb that subtends an angle of  $32''.4$ .

The amount of the error of graduation has been found as follows:—

In Colonel Campbell's observations at eight stations, his mean Z. D. was  $5^\circ 54' 30''$ , and his mean (N—S) difference was  $2''.125$ : that is, his final value of latitude deduced from north stars of a mean Z. D. of  $5^\circ 54' 30''$  was smaller by  $2''.125$  than his final value of latitude deduced from south stars of a mean Z. D. of  $5^\circ 54' 30''$ : thus both his north and south zenith distances (of  $5^\circ 54' 30''$ ) were each measured too large by  $\frac{2''.125}{2}$ . Colonel Campbell's observations thus give the error of the limb graduation to be  $1''.063$  in  $5^\circ 54' 30''$ , from which the following corrections can be deduced: (i). An angle of one degree is shown by the graduations on the limb as  $1^\circ 0' 0''.18$ ; (ii) an angle of  $0^\circ 1' 0''.00$  is graduated on the limb as  $0^\circ 1' 0''.003$ ; (iii) an angle of  $1''$  is shown on the limb as  $0^\circ 0' 1''.00005$ .

From my observations this season, the (N—S) difference is given at  $2''.50$  for a mean Z.D. of  $6^\circ 39'$ : from these data the amount of limb error is given as  $0''.186$  for each degree,  $0''.0031$  for each minute, and  $0''.000052$  for each second.

Colonel Campbell's results have been used to deduce a "limb correction," and every *observed* zenith distance has been decreased by  $0''.18$  for each degree,  $0''.003$  for each minute, and  $0''.00005$  for each second. This correction has been applied to observations taken this season by the sector method, and has brought them into accordance, eliminating all signs of a (N—S) equation.

# APPENDIX.

## No. 4.

### ON THE VALUE OF THE MICROMETER OF THE ZENITH TELESCOPE.

BY CAPTAIN H. McC. COWIE, R.E.,  
In charge of the Astronomical Party.

#### 1.

*A comparison of values determined by independent methods.*

In 1902-03 the micrometer value was determined at five stations from measurements of known differences of declination.

Station	Value for one Revolution		Difference
	Which renders the latitude observations most accordant	Determined from observations of declination	
Gúrmi ... ..	69.2327	69.2087	+ 0.0240
Majhár ... ..	.2115	...	...
Algi ... ..	.2116	.2116	0.0000
Andhjári ... ..	.2258	.2270	- 0.0012
Budhon ... ..	.2191	.2294	- 0.0103
Dargawa ... ..	.2387	.2305	+ 0.0082
Saugor ... ..	.2185	...	...
Náharmau ... ..	.2155	...	...
Mean ... ..	69.2217	69.2214	+ 0.0003

In order to eliminate from the final latitudes errors due to the use of an incorrect value, positive and negative micrometer quantities have been equalised, and the residual correction entering into the final result of the observations reduced to a minimum.

The differences shown in the above table between the values deduced from the latitude results and those determined by independent observations may be due to a combination of the following sources of error:—

(1). In the independent observations only micrometer wire B is used and in consequence the length of screw involved is from 20 to 40 revolutions.

In the latitude observations when the auxiliary wires A and C are utilized, the intervals AB and BC being approximately each 10 revolutions, a length of screw greater than 15 or 16 revolutions is rarely necessary. It is not difficult to suppose that the accumulated systematic errors of the 40 revolutions used in the first case, differ from those of the central 16 revolutions employed in the latitude observations, and consequently it is to be expected that the respective values for the micrometer given by the two methods should differ slightly.

(2). When the auxiliary wires A and C are made use of in the latitude observations, the value of the interval (A—C) will enter as a correction always of one sign when the micrometer correction is positive and always of the other sign when the correction is negative. Consequently the result of a discussion of the respective latitude values given by positive and negative micrometer corrections will be in error unless the interval (A—C) is known absolutely exactly.

(3). In consequence of the changes in the objective, in the telescope tube and in the micrometer screw owing to variations of temperature, unless the mean temperature during the latitude operations is the same as that for the independent micrometer observations, the values for a revolution of the screw deduced by the different methods will not agree.\*

There is still another complication introduced in consequence of the effect of changes of temperature. The auxiliary wires A and C are carried by the brass sliding plate of the micrometer, actuated by the steel screw. The determination of the value AC in terms of the screw is made at a certain temperature. The value so determined is correct for that temperature only and by using it for observations taken at any other temperature, errors are introduced.\* The method of determining this interval is such that it is difficult to get satisfactory results when the field is lighted only faintly by the axis lamp. It has therefore been usual to measure the interval during the day. If we suppose the temperature during the day observation to differ from the night temperature during the latitude operations an error will be introduced into every result obtained from observations into which the (A-C) interval enters. The sign of this error will be according as the sign of the (A-C) reduction is positive or negative and as the change of temperature is a fall or a rise.

From this it is apparent that it is not sufficient to balance positive and negative micrometer quantities without having regard at the same time to the number of times that AC enters as a positive and as a negative quantity. As well as balancing positive and negative corrections, we should effect cancelment of positive and negative (A-C) intervals.

I am of opinion, in view of the complications they introduce, that the advantages which these auxiliary micrometer wires exhibit in respect to convenience in observing and reduction of the wear of the screw, do not quite justify their employment.

## 2.

*The examination of the micrometer screw of the Zenith Telescope under "G" microscope and the effect the errors, thus determined, would have on the micrometer correction.*

The micrometer, detached from the zenith telescope, was securely mounted on one of the gun-metal "camels" of the apparatus for the comparison of standards, by means of which it could be moved vertically and also horizontally in the line of the micrometer screw. The microscope "G" was then mounted on one of the isolated masonry pillars of the Bar Room and adjusted as for the comparison of standards.

The camel carrying the micrometer was next placed under "G" in such a way as to bring the screw of the micrometer as nearly as possible parallel to the screw of the microscope "G". As only relative values for each revolution were required, it was not necessary that the two screws should be absolutely parallel; it was sufficient if the directions of motion in the two micrometers were so nearly parallel that the same part of "G"'s micrometer wire would always coincide with the same part of the zenith telescope wire.

The apparatus having been carefully prepared, "G" microscope adjusted, and the zenith telescope micrometer levelled in position, with its wire illumined and clearly focussed in the microscope, the observations were commenced. The procedure was as follows:—

"G" was set to a convenient reading about the centre of the field. The zenith telescope wire, B, was then set to the reading 35·00 revolutions, and by means of the "camel" screw, the whole micrometer traversed horizontally until B came into position between the two parallel intersecting wires of "G". The mean of several readings of "G" was then determined, corresponding to this position of the wire B. The zenith telescope micrometer was now set to read 36·00 revolutions and for the new position of B, a corresponding mean reading of "G" determined. The difference of the two readings thus gave a value in terms of "G" for the revolution 35 to 36.

"G" microscope was next set at its first reading,—that for zenith telescope 35·00—and the zenith telescope micrometer remaining at the setting 36·00 revolutions was traversed horizontally, until B again came into position between the wires of "G". Readings were now taken as before for the revolution 36 to 37. This procedure was followed until the setting 65·00 revolutions was arrived at.

In this way values for each revolution of the zenith telescope micrometer between readings 35·00 and 65·00 were obtained in terms of the same portion of the screw of "G" microscope.

One complete set of observations having been taken the whole apparatus was dismantled, re-erected, the illumination changed and a second series of measures made; this time the observations were commenced with the zenith telescope reading 65·00 and finished at 35·00 revolutions.

Three series of observations were made in this way. Each value was then reduced to terms of the mean of the series to which it belonged, the mean being put equal to unity. The resulting quantities for each series are shewn in columns 2, 3 and 4 of Table A.

\* See penultimate paragraph, page (6), Chapter I of this Volume.

Column 5 gives the mean value for each revolution, and column 6 the difference of each from the mean revolution.

The values in column 6 were then plotted and a smooth curve drawn to represent these observed quantities. Column 7 gives the final errors of each revolution as measured from the curve. These quantities represent the difference of each from the mean revolution for that portion of the screw lying between readings 35 00 and 65 00. Column 8 gives the accumulated errors.

Table A.

Before enquiring into the effect of the systematic errors it is necessary to ascertain the quantities entering into the micrometer correction and the methods by which they are determined.

In the micrometer of the zenith telescope, the travelling frame carries three wires  $A, B$  and  $C$  at intervals of approximately 10 revolutions. When intersecting a star, use is made of the wire lying nearest to it as it crosses the field, but the reading taken from the micrometer is the reading for the central wire  $B$ . Consequently to determine the true micrometer reading for an observation to a star, it is necessary to apply to the recorded reading of  $B$ , the value of the interval between  $B$  and the wire used. The corrected quantity for the intersection of a star is then of the form  $B \pm i$  according as the wire  $C$  or  $A$  is used, and the difference of the micrometer readings for the two stars of a pair,—the quantity entering into the micrometer correction in the reduction of an observation for co-latitude,—will be of the form

$$(B_w \pm i_w) - (B_c \pm i_c)$$

the sign  $\pm$  being according as the wire  $C$  or  $A$  was used in intersecting the star.

This general form covers four individual cases :

- (a) when  $B_w$  is greater than  $B_c$  and wire  $C$  is used with  $B_w$  and  $A$  with  $B_c$ .
- (b) when  $B_w$  is greater than  $B_c$  and wire  $A$  is used with  $B_w$  and  $C$  with  $B_c$ .
- (c) when  $B_w$  is less than  $B_c$  and wire  $C$  is used with  $B_w$  and  $A$  with  $B_c$ .
- (d) when  $B_w$  is less than  $B_c$  and wire  $A$  is used with  $B_w$  and  $C$  with  $B_c$ .

In the cases (a) and (c) expression (a) takes the particular form

$$(B_w - B_c) + (i_w + i_c)$$

and since the wire  $A$  is never used for an intersection at a point above and the wire  $C$  never for an intersection below 50°00' ( $\beta$ ) is always a positive quantity.

In cases (b) and (d) equation (a) becomes

$$(B_w - B_c) - (i_w + i_c)$$

which is always a negative quantity. Thus it appears that of those micrometer corrections of which the  $A$  and  $C$  intervals form a part, into such as are positive, the values of these intervals enter as positive quantities and into those that are negative, as negative quantities.

Only a very few co-latitude observations do not involve the use of either wire  $A$  or wire  $C$ . In over 80 per cent, both wires are used. In the great majority of cases, then, the micrometer correction is composed of two quantities, one of which is actually measured on the screw, the other being the interval between the wires used in the two star intersections.

Let the micrometer correction applied in the reduction of observations for co-latitude be represented in amount by

$$\frac{1}{2} (M + I) \mu.$$

where  $M$  is the quantity  $B_w - B_c$ , actually measured on the screw.

$I$  the quantity  $i_w + i_c$ , the sum of the wire intervals:

$\mu$  the value of a mean revolution of the micrometer.

If  $M$  be supposed in error by  $\delta M$ ,

$$I \quad \quad \quad \delta I,$$

$$\mu \quad \quad \quad \delta \mu,$$

The true correction would be

$$\frac{1}{2} (M + I + \delta M + \delta I) (\mu + \delta \mu).$$

The applied correction is in error by

$$\frac{1}{2} (\delta M + \delta I) (\mu + \delta \mu) + \frac{1}{2} (M + I) \delta \mu.$$

The term

$$\frac{1}{2} (\delta M + \delta I) \delta \mu \text{ is negligible.}$$

and the error in the applied correction may be taken as

$$\frac{1}{2} (\delta M + \delta I) \mu + \frac{1}{2} (M + I) \delta \mu$$

The quantity  $M$ , measured on the central portion of the screw, is distributed equally on either side of the point 50.00, the reference point of the micrometer. As regards its magnitude, a consideration of a number of records has given the following results:

In 18 per cent of observations  $M$  lies between 0 and 5 revolutions.

19	„	„	„	„	5	„	10	„
25	„	„	„	„	10	„	15	„
18	„	„	„	„	15	„	20	„
8	„	„	„	„	20	„	25	„
8	„	„	„	„	25	„	30	„
4	„	„	„	„	over 30			

It appears that the most frequently occurring value of  $M$  is 12 revolutions. Suppose  $M$  to be 12 revolutions, that is, to have been measured on the portion of screw between readings 44.00 and 56.00.

From column 8 of Table A the systematic error of screw accumulated

at 44.00 is — 1.26 divisions

at 56.00 „ — 1.75 „

The table thus shows that the portion of screw from revolution 44 to revolution 56 is equal to

12 mean revolutions — 0.49 division.

The quantity  $M$  which from the difference of the micrometer readings appears to be 12 revolutions is, then, too large by 0.49 division.

$$\delta M = + 0.49 \text{ division.}$$

A consideration of the method by which the intervals  $AB$  and  $BC$  are determined will at once show that these quantities cannot be measured in terms of any particular portion of the screw we please. The portion of the screw involved is regulated by the position of the “speck” selected as the reference point. It thus has happened that for many seasons the interval  $AB$  has been determined in terms of revolutions 45 to 55 and  $BC$  in terms of revolutions 46 to 56.

Table A gives the systematic errors of these portions of the screw.

The accumulated error at revolution 45 is — 1.26 divisions.

„ „ „ 55 — 1.85 „

The portion of screw between revolutions 45 and 55 is then less than 10 revolutions by 0.59 division, and the value  $AB$  deduced from the micrometer readings is too large by 0.59 division.

The value of  $BC$  similarly appears to be too large by 0.44 division.

The quantity  $I$  is therefore too large by 1.03 divisions.

$$\delta I = + 1.03 \text{ divisions.}$$

In the last few seasons, the programme of observations for the determination of the micrometer value has been framed so as to deal particularly with the 30 central revolutions—that is, from revolution 35 to revolution 65. Hence for these seasons  $\mu$  may be considered as fairly representing the standard revolution of Table A and  $\delta \mu$  as an accidental error of observation.

The errors in the applied micrometer correction, due to systematic errors of the screw, are, as given above,

$$\frac{1}{2} (\delta M + \delta I) \mu + \frac{1}{2} (M + I) \delta \mu$$

In which the quantity  $\delta I$  has been shewn to be a constant error for all micrometer corrections of like sign. Taking the value of  $\mu$  to be  $69''$  and  $\delta I$  as determined above.

$$\frac{1}{2} \delta I \mu = 0'' \cdot 36.$$

If we take as an example

$$M = 12 \text{ revolutions,}$$

$$\text{then } \delta M \text{ is } = + 0 \cdot 49 \text{ division :}$$

$$\text{also taking } \delta \mu = 0'' \cdot 01 \text{ an extreme value,}$$

the values of the terms of the expression above are seen to be

$$\frac{1}{2} (\delta M + \delta I) \mu = + 0'' \cdot 52$$

$$\frac{1}{2} (M + I) \delta \mu = 0'' \cdot 16.$$

The Table *A* gives the following values for  $\delta M$  for different values of  $M$ .

$M$ in Revolutions	$\delta M$ in divisions	$\delta M$ in seconds of arc
2	+ 0·22	+ 0''·15
4	+ 0·41	+ 0·28
6	+ 0·54	+ 0·37
8	+ 0·60	+ 0·41
10	+ 0·59	+ 0·40
12	+ 0·49	+ 0·34
14	+ 0·28	+ 0·19
16	+ 0·04	+ 0·03
18	− 0·09	− 0·06
20	− 0·06	− 0·04
22	+ 0·06	+ 0·04
24	+ 0·18	+ 0·12
26	+ 0·22	+ 0·15
28	+ 0·16	+ 0·11
30	0·00	0·00

From this it is seen that to all intents  $\delta M$  is constant in sign—that sign being the same as for  $\delta I$ .

The error  $\frac{1}{2} (\delta M + \delta I) \mu$  is then constant in sign for all micrometer corrections of like sign, and varies in amount from  $0'' \cdot 56$  to  $0'' \cdot 33$  according to the value of  $M$ .

All positive micrometer corrections are thus burdened with an error of constant sign and all negative corrections similarly affected by an error of opposite sign. In consequence, the consideration of the values for the co-latitude given respectively by  $+$  and  $-$  micrometer corrections with the object of determining the quantity  $\delta \mu$  can lead to no reliable result, until the systematic errors of the screw have been determined and corrections for them applied in the reduction of the observations for latitude.

## No. 5.

### ON THE AZIMUTH OBSERVATIONS OF THE GREAT TRIGONOMETRICAL SURVEY OF INDIA.

BY

LIEUT.-COL. S. G. BURRARD, R.E., F.R.S.,  
*Superintendent of Trigonometrical Surveys.*

(1). From 1802 to the present time rigorous astronomical observations for azimuth have been regularly taken at stations of the Principal Triangulation. The practice has been for the officer conducting the triangulation to observe for azimuth himself at every 40 or 50 miles. Although much time and trouble have in the aggregate been expended on the measurements and reductions, no use has so far been made of the undoubtedly valuable results. In this paper I have attempted to analyse the geodetic evidence furnished by our azimuth observations but I have not been wholly convinced that my investigation is worthy of publication. I have decided to publish it, firstly, because the results though imperfect are perhaps as good as are obtainable from present data, and secondly, because the narrative will place on record for future use the obstacles encountered, will explain the causes of failure, and will indicate the remedial steps, that will have to be taken as soon as observers are available.

(2). *The purposes served by Azimuth Observations.* In a geodetic survey astronomical observations for latitude and longitude serve two purposes, the measurement of the earth's axes, and the determination of the local direction of gravity. An azimuth observer has, however, no less than three objects in view, the measurement of the earth's axes, the determination of the local direction of gravity, and the deduction of the azimuthal error accumulated in the triangulation.

In comparing the values of latitude and longitude calculated through the triangulation with the observed values, we are confronted with the difficulty, that each difference is made up of two component parts, which we are required to separate: but a difference between an observed and a calculated azimuth has no less than three entangled components.

(3). 1799-1823. Azimuth observations were taken by Colonel Lambton *for the purpose of determining the figure of the earth from arcs perpendicular to the meridian.* In his day the figure of the earth was not known to any degree of certainty, and in all probability the discrepancies then between geodetic and observed azimuths were mainly due to the errors in the adopted values of the earth's axes. Lambton did not utilise his observed azimuths to determine either deflections of the plumb-line or errors of triangulation.

(4). 1823-1843. Colonel Everest regarded observed azimuths as checks upon the accuracy of the triangulation. On page 84 of his *Account of the Measurement of an Arc &c.*, 1830, he describes an observation for azimuth at Takalkhera, and computes from it with the aid of the triangulation an azimuth at Kaliánpur. "We get", he writes, " $10^{\circ} 27' 32'' \cdot 170$ " for the computed azimuth of Soorental at Kullianpoor. But from twenty-seven observations of circumpolar stars the "azimuth \* \* \* is observed to be \* \* \*  $10^{\circ} 27' 30'' \cdot 717$ ." "The difference of  $1'' \cdot 453$  is", he says, "a quantity quite within the limits to which so extensive a series could be expected to arrive."

In his determinations of the figure of the earth Colonel Everest took great pains to refer the sides of his triangles to the meridian before deducing the terrestrial arc: to carry out this operation he required an accurate knowledge of the azimuth of the triangulation, and he introduced several observed azimuths as "verificatory of each other."

He did not however regard his azimuth at Banog as verificatory: to the north-east of this station, he pointed out, were the Himalaya Mountains with nought on the south-west to counterbalance them but a flat plain: "the principal attraction", he wrote, "being on the north-eastern side, the tendency would be to make the observed azimuths less than those brought up by computation: whether the error of  $4\frac{1}{2}$  seconds noted at Kaliaha has arisen from an accumulation of errors in the observed angles or is also attributable to the same cause it is impossible to say. I had hoped to have placed that station far enough to be beyond the influence of that irregularity."\*

---

\* See *Account of the Measurement of two Sections of the Meridional Arc of India, 1847, Introduction, page xlii.*

(5). 1858. When the figure of the earth was being determined by Col. Clarke from the triangulation of Great Britain, an equation of condition was formed from each observed azimuth, and the azimuthal errors of the triangulation were neglected. Discussing these equations on page 293 of his work on Geodesy, Col. Clarke writes:—

“The azimuth and longitude equations are from the nature of those observations entitled to much less weight than the latitude equations: the azimuth equations in particular are directly affected by accumulation of errors of the “observed angles of the triangulation.”

(6). 1861-1884. In General Walker's time azimuth observations had come to be regarded in practice as determinations of the direction of gravity. Thus the fundamental azimuth at Kaliánpur was derived from a surrounding group of observed azimuths treated by the method of minimum squares: such a course could not have been pursued except on the assumption that the differences treated between observed and geodetic azimuths were due to accidental and local attractions.

Moreover the closing errors of the great circuits of the Principal Triangulation were adjusted by the method of minimum squares, and this course would not have been adopted, had it been suspected that the whole triangulation was being deflected from the true direction by an ever-increasing azimuthal error: for would it not have been considered inconsistent to introduce the complicated machinery of minimum squares to adjust the closing errors of circuits, which in South India averaged 2" in amount\*, if it had been suspected that the whole of the South Indian Triangulation was in error by 6" in azimuth†?

The following extracts from chapters xi and xii of Volume II of the *Account of the Operations of the Great Trigonometrical Survey of India* show General Walker's opinions:—

“The difference between the observed azimuth of any line at a station *B* and the geodetic azimuth of the same line as brought up through the triangulation from a fundamental station *A*, may be due either to local deflections of the plumb-line at *A* and *B*, or to errors in the astronomical determinations of the azimuths at those stations, or to errors in the connecting triangulation; very possibly all three causes operate in every instance, but it is impossible to disentangle them, and determine the value of each separately; practically the only thing to be done is to assume the astronomical observations and the triangulation to be errorless, and that the entire difference is due to deviations of the plumb-line.”

“It will be seen that there is a large number of stations at which astronomical determinations of latitude and azimuth have already been made, and the number of these may be expected to be somewhat increased before the triangulation is completed; besides these there are a few stations at which electro-telegraphic differences of longitude have already been made, and several at which they will probably be made hereafter. But all these observations are liable to be influenced by local deflections of the plumb-line to a greater extent than the principal triangulation of the Survey is liable to be influenced by errors generated in the measurement of the angles. The differences between the direct determinations of the elements of any station and the computed values brought up to it from the origin, are due to errors of operation, to errors in the adopted elements of the figure of the earth, and to local deflections of the plumb-line; and of all these causes the last is, in this Survey, the most significant.”

In his paper entitled *India's Contributions to Geodesy* and published in the *Philosophical Transactions of the Royal Society* in 1895, General Walker made no use of the Indian observed azimuths.

(7). In 1897 Capt. Lenox Conyngham, R.E., pointed out that the large differences between astronomical and geodetic azimuths, which obtained in South India, could not be attributed to local attractions.

(8). In 1900 I commenced a classification of all deflections of the plumb-line observed in India; and as more latitudes had been observed than longitudes I decided to equalise the numbers of deflections in the meridian and of those in the prime vertical by including the observed azimuths. I was not then conversant with the investigations carried out at Potsdam and published in *Lothabweichungen, Heft I: 1886* and in *Die Europäische Längengradmessung von Greenwich bis Warschau von Börsch and Krüger 1896*. I was only aware of what Colonel Clarke had written in chapter xii of his *Geodesy*; on page 291 he shows that “the observation of the difference of longitude gives us no information that is not also given by the observation of azimuth.”

In appendix No. 2 to my paper on Himalayan attraction published in 1901, the azimuth observations of India were compiled and classified.

It was then found that at a few stations both longitude and azimuth observations had been taken. The two methods of observation, it was at once seen, did not yield accordant values of the deflection of the plumb-line, and it required but little insight to discover that the differences between the astronomical and calculated values of azimuth were largely due to the effect on the latter of the azimuthal errors accumulated in the triangulation.

The conclusion that I arrived at was that, though the difference in azimuth between two rays can be more accurately determined by triangulation than by astronomical observations when the rays are not distant from one another, yet the errors of triangulation tend to accumulate and at great distances from the origin the accumulated error of the triangulation may easily exceed the error that local attraction is liable to produce in an observed azimuth.

\* Volumes XII and XIII of the *Account of the Operations of the G. T. Survey of India*.

† Survey of India.—Professional Paper No. 5 of 1901, part I, page 18.

On page 17 of the paper on Himalayan attraction will be found my first attempt to determine the azimuthal errors of the principal triangulation from comparisons of longitude and azimuth results. I had fully intended in that paper to take a step further and, by applying corrections to the geodetic azimuths, to render the azimuthal observations available for a discussion of the direction of gravity. But this course was not practicable: our azimuth observations had been taken on one plan by the triangulation parties and our longitude observations on another by independent astronomical parties, and when the results came to be compared, but three stations were found at which both an azimuth and a longitude had been observed. Colonel Clarke's proof that an observation of longitude gave no information that was not also given by an observation of azimuth had led observers to believe that the determination of both longitude and azimuth at one station would be a somewhat unprofitable duplication of results.

Nevertheless the table published on page 18 of the paper on Himalayan attraction gave a fair indication of the magnitude of the azimuthal errors of the triangulation: and this table convinced me that the azimuth observations accumulated by our survey would never be of use to anyone, until we had observed both for azimuth and longitude at a great number of selected stations. I had to abandon for the time all idea of utilising the observed azimuths: it was perhaps a first step to have got a complete list of azimuths compiled, but the possibility of making use of them seemed as far off as ever.

(9). *The supplementary Azimuth Observations of 1903-5.* Azimuth observations are simpler than those of longitude; they occupy less time and require but one observer; in order to supply the data that had been found wanting, it appeared at first sight only necessary to arrange for an azimuth to be observed at every longitude station, and in 1903 Captain H. Wood, R.E. undertook this task.

At the commencement of his work however a new difficulty was encountered. The longitude stations were selected by our predecessors for the purpose of measuring arcs of parallel and a comparison of longitude and azimuth results was not contemplated. The selection of longitude stations was based on two principles: (i) India was to be covered by a network of equal triangles formed by longitude arcs: (ii) each longitude station was to be placed at an important telegraph office.

The telegraphs of India have been widely extended since our longitude arcs were planned, and now-a-days we should possibly not experience much difficulty in obtaining "through" telegraphic communication from one longitude station to another, even if they were located at small telegraph offices. But formerly it was considered desirable to place each longitude station at a large central telegraph office where the telegraph master was of superior rank and able to order "through" communication and to prevent minor offices from breaking in.

The longitude stations were consequently often located at distances from the principal triangulation, and their geodetic positions were determined by secondary chains carried from the nearest stations of the principal triangles. It will be seen from the Appendices to Volumes IX and X of the *Account of the Operations of the Great Trigonometrical Survey of India* that triangular errors of 3" and 5" were common in the very small triangles which generally closed the secondary chains in the hearts of towns.

(10). In justice to our predecessors we have to admit that the special chains of secondary triangles satisfied all the requirements of the immediate object in view, viz., the determination of the lengths of the earth's axes from the measurements of arcs of parallel. The use to which we are now putting our longitude observations was not considered in the original scheme.

The probable error of an observed arc of longitude is seldom less than  $0''.05$ : and it is consequently unnecessary to determine the geodetic longitude of the arc's terminals to a greater degree of accuracy than 2 or 3 feet. The triangles in which triangular errors of 3" and 5" occur are invariably small; their sides are perhaps one or two miles in length and few only of such triangles occur in any single chain: it is consequently unlikely that the geodetic longitudes have been affected to a larger extent than one or two feet. A geodetic difference of longitude and a geodetic azimuth are both angular measurements, but they are affected in a different way by a linear displacement. The resulting error in the longitude is represented by the angle which the station's displacement subtends at the pole; the resulting error in the azimuth is the angle, which the station's relative displacement subtends at the next station of the triangle, distant perhaps a mile. In a triangle with an area of half a square mile and with a triangular error of 5" the stations are fixed correctly within an inch, and are suitable for longitude work; but the azimuths of the sides are not known within 2" or 3" and are useless for geodetic purposes.

(11). To revise the secondary triangulation with which longitude stations had been fixed was found to be no simple matter. The longitude stations had been located in the gardens of telegraph offices near the centres of cantonments and cities: no triangulation would have been possible, until many valuable trees had been cut down, and even if these clearances had been sanctioned, the view would still have been obstructed by houses, which would have rendered small triangles necessary. Moreover in the case of some stations the chains of triangulation requiring revision were long; Mooltan was 46 miles from a principal station; Peshawar was 106 miles.

It is true that the secondary chains connecting these places with principal series had been, with the exception of their small terminal triangles, well-observed, but still they were secondary, and having regard to the accumulation of error in long chains I came to the conclusion, that if they were to be revised at all, they ought to be revised entirely.

With principal triangulation urgently required in Burma and Baluchistan, there is practically no early prospect of our being able to carry out the revisions to longitude stations, and in my opinion it will be better to extend the

longitude work to the existing principal triangulation than to extend the triangulation to the existing longitude stations: it will too be cheaper to select new longitude stations and to observe new longitude arcs. When therefore two astronomical observers are next available, and the long prospected longitude arcs of Burma come to be undertaken, the utilisation of our azimuths should be kept in view, and supplementary longitude stations should be selected at the critical points of our principal triangulation.

(12). Meanwhile Capt. Wood had to proceed with his programme of azimuths and to make the most of the secondary triangulation at his disposal. His original intention had been to observe for azimuth over the marks of the longitude stations, but this ideal procedure he was unable to carry through, and he had to fall back on a compromise.

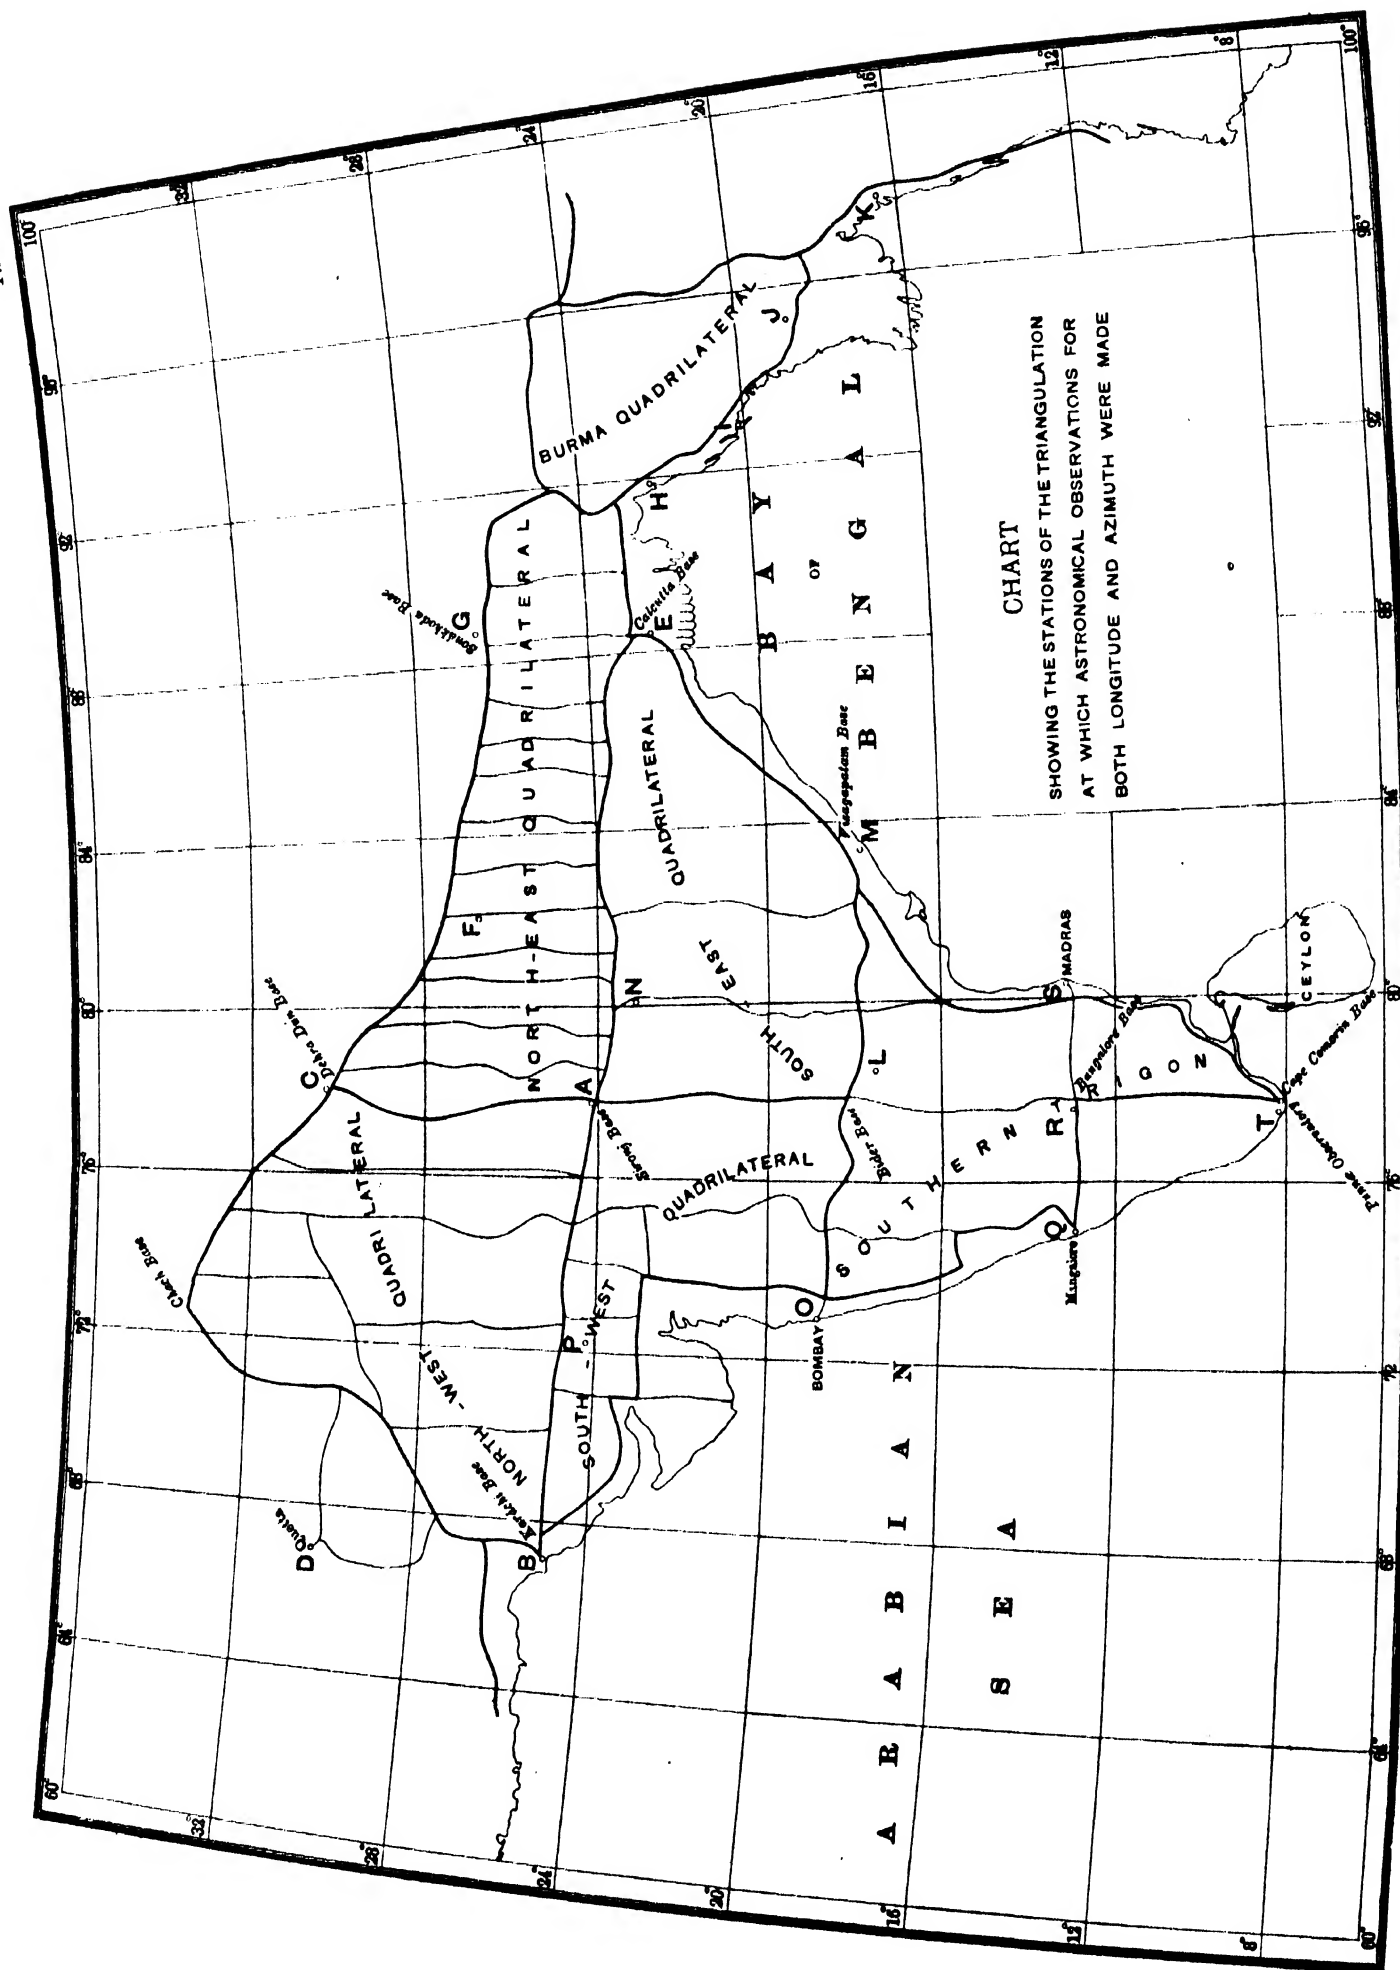

Let us suppose that a longitude station is situated on a flat plain in the heart of a city, and that the principal triangulation has determined an accurate geodetic azimuth at a station two miles distant outside the walls. To observe for azimuth at such a longitude station is useless, because the geodetic azimuths of the sides of the small urban triangles are not known within 2" or 3"; the only simple way out of the difficulty is to observe for azimuth at the nearest station of the principal triangulation, and then to compare the resulting deflection of gravity with the deflection at the longitude station itself. In following such a course we are abandoning our ideal plan, and we are making the assumption that the local attraction is identical at both stations. Such an assumption would perhaps be admissible if the two stations were near each other, if the country was flat, and if no geological disturbances were apparent; but the maximum permissible interval between longitude and azimuth stations, whose results are to be used for the formation of Laplace's equation, is not a subject suitable for discussion. There ought, we know, to be no interval: that is the only proper course and every other is a make-shift.

In order to secure a reliable value of geodetic azimuth in the case of weak terminal triangles, Captain Wood was authorised to admit an interval of 5 miles between the longitude and azimuth stations, when the country was flat, and one of 2 miles when hills were visible on the horizon: in hilly country no interval was regarded as permissible.

Captain Wood was unable to observe for azimuth at all the longitude stations in one field season, and on his return it was found that his result at Promé rendered an intervening Laplace station between India and Burma necessary; in 1904 Captain H. McC. Cowie, R.E. was able to furnish such a station by observing for azimuth near Chittagong.

(13). Table I shows the stations at which Laplace equations have been formed: Table II shows the longitude stations which were too far from the principal triangulation to be utilised. The positions of the stations of Table I are shown on the attached chart.

Note.— The letters A, B, C, &c. refer to the Stations given in Table 1 of Appendix 5.

TABLE I.—Names and Descriptions of accepted Stations.

Reference Letter	Longitude Station		Nearest Azimuth Station	Distance between Longitude and Azimuth Stations		Description of surrounding country

(14). *General Walker's initial azimuth.* We have for our data the results of longitude and azimuth observations at 20 stations: but before we can proceed to form equations we have to consider another difficulty. When the calculations of the principal triangulation were being undertaken, General Walker deduced a value for the initial azimuth from a great group of observed azimuths. In taking this step General Walker hoped to free the fundamental azimuth, on which the orientation of the whole triangulation depended, from the effects of local attraction. The course pursued has since been regretted: the complications introduced have added greatly to the difficulties of subsequent investigation, and nothing was gained, for we now realise that the initial azimuth at Kaliánpur was not freed from the effects of local attraction.

When in India we compare a geodetic and an observed difference of *longitude*, the observed difference is measured from the astronomical meridian of Kaliánpur: but when we compare a geodetic and an observed *azimuth*, the geodetic azimuth has been brought up from Walker's meridian at Kaliánpur, and this meridian is not coincident with the astronomical meridian.

For purposes of this investigation I have had to adopt a new value of the initial azimuth and to recompute through the triangulation all the geodetic longitudes and azimuths employed. The value of initial azimuth now adopted is  $190^{\circ} 27' 6''.29$ , being the mean of the observed values as deduced on page 7 of Professional Paper No. 5 of 1901. In the comparisons now to be instituted between longitude and azimuth results both sets of observation will be referred to the astronomical meridian at Kaliánpur.

This course has the disadvantage of bringing into use different geodetic values of longitude and azimuth from those published in our preceding volumes. Every member of an old survey knows the objections to incessant changes of data; and I hope it will be clearly understood that no general recomputation is at present contemplated, and that the geodetic data in the following tables have been only deduced for the one particular purpose.

Notes.—T.O. denotes Telegraph Office. H.S. denotes Hill Station, principal. T.S. denotes Tower Station, principal. P.S. denotes Platform Station, principal.

\* By the "Bessel-Clarke Spheroid" is meant the spheroid which results from a combination of the major axis of Clarke and the ellipticity of Bessel.

† It will be found that the quantities in this column do not agree exactly with the values published on page 17 of Professional Paper No. 5 of 1901: the discrepancies have arisen, firstly, because the observed azimuths in Table IV above have been recomputed with the latest values of declination, secondly, because the observed azimuths have now been corrected for aberration, and, thirdly, because the geodetic azimuths in Table II have been calculated from the astronomical meridian at Kaliánpur instead of from an assumed meridian.

**TABLE V.—Deflections of the plumb-line in the prime vertical deduced from comparisons of Observed and Geodetic differences of Longitude.**

(16). We have now deduced the azimuthal errors of the triangulation at several points : our remaining tasks are :—

- to determine by interpolation the azimuthal errors of the triangulation at intermediate azimuth stations.
- to correct the geodetic azimuths at these stations for the errors so determined.
- to deduce finally the deflection of the plumb-line in the prime vertical from comparisons between the corrected geodetic and the observed azimuths.

In Table VII these last steps have been taken.

Notes.—T.O. denotes Telegraph Office. H.S. denotes Hill Station, principal. T.S. denotes Tower Station, principal. S. denotes Station, principal, in the plains. s. denotes station, secondary, in the plains.

**TABLE VII.—Final deduction of deflections of the plumb-line from azimuth observations, the geodetic azimuths being based on the observed azimuth at Kálánpur and corrected for errors accumulated in the triangulation. The Spheroid of reference is that of Everest.**

# APPENDIX.

## No. 6.

### A CATALOGUE OF THE PUBLICATIONS OF THE GREAT TRIGONOMETRICAL SURVEY OF INDIA.

*An Account of the Measurement of an Arc of the Meridian between the parallels of  $18^{\circ} 3'$  and  $24^{\circ} 7'$ , being a continuation of the Grand Meridional Arc of India, as detailed by the late Lieut.-Colonel Lambton, in the Volumes of the Asiatic Society of Calcutta. London, 1830.\**

*An Account of the Measurement of two Sections of the Meridional Arc of India, bounded by the parallels of  $18^{\circ} 3' 15''$ ;  $24^{\circ} 7' 11''$ ; and  $29^{\circ} 30' 48''$ . London, 1847.\**

### Account of the Operations of the Great Trigonometrical Survey of India :

*Vol. I. The Standards of Measure and the Base-Lines, also an Introductory Account of the early Operations of the Survey during the period 1800-1830. Dehra Doon, 1870.\**

Appendix No. 1. Description of the method of comparing, and the apparatus employed.

Appendix No. 2. Comparisons of the Lengths of 10-foot Standards A and B, and determinations of the Difference of their Expansions.

Appendix No. 3. Comparisons between the 10-foot Standards B 1s and A.

Appendix No. 4. Comparisons of the 6-inch Brass Scales of the Compensated Microscopes.

Appendix No. 5. Determination of the Length of the Inch [7.8] on Cary's 3-foot Brass Scale.

Appendix No. 6. Comparisons between the 10-foot Standard Bars 1s and A for determining the Expansion of bar A.

Appendix No. 7. Final determination of the Differences in Length between the 10-foot Standards B 1s and A.

Appendix No. 8. On the Thermometers employed with the Standards of Length.

Appendix No. 9. Determination of the Lengths of the Sub-divisions of the Inch [a. b].

Appendix No. 10. Report on the Practical Errors of the Measurement of the Cape Comorin Base.

*Vol. II. History and General Description of the Principal Triangulation and of its Reduction. Dehra Dún, 1879.\**

Appendix No. 1. Investigations applying to the Indian Geodesy.

Appendix No. 2. The Micrometer Microscope Theodolites.

Appendix No. 3. On Observations of Terrestrial Refraction at certain stations situated on the plains of the Panjab.

Appendix No. 4. On the Periodic Errors of Graduated Circles, &c.

Appendix No. 5. On certain Modifications of Colonel Everest's System of Observing introduced to meet the specialities of particular instruments.

Appendix No. 6. On Tidal Observations at Kurrachee in 1855.

Appendix No. 7. An alternative Method of obtaining the Formulæ in Chapters VIII and XV employed in the Reduction of Triangulation.—Additional Formulæ and Demonstrations.

Appendix No. 8. On the Dispersion of Circuit Errors of Triangulation after the Angles have been corrected for Figural Conditions.

Appendix No. 9. Corrections to Azimuthal Observations for imperfect Instrumental Adjustments.

Appendix No. 10. Reduction of the N. W. Quadrilateral—the Non-Circuit Triangles and their Final Figural Adjustments.

Appendix No. 11. The Theoretical Errors of the Triangulation of the North-West Quadrilateral.

Appendix No. 12. Simultaneous Reduction of the N. W. Quadrilateral—the Computations.

*Vol. III. The Principal Triangulation—the Base-Line Figures, the Karáchi Longitudinal, N. W. Himalaya, and Great Indus Series of the North-West Quadrilateral. Dehra Doon, 1873.\**

*Vol. IV. The Principal Triangulation—the Great Arc (Section  $24^{\circ}$ - $30^{\circ}$ ), Rahún, Gurhagarh and Jogí-Tila Meridional Series and the Sutlej Series of the North-West Quadrilateral. Dehra Dún, 1876.*

*Vol. IVA. General Description of the Principal Triangulation of the Jódhpore and the Eastern Sind Meridional Series of the North-West Quadrilateral, with the Details of their Reduction and the Final Results. Dehra Dún, 1886.*

*Vol. V. Details of the Pendulum Operations and of their Reduction. Dehra Dún and Calcutta, 1879.*

Appendix No. 1. Account of the Remeasurement of the Length of Kater's Pendulum at the Ordnance Survey Office, Southampton.

Appendix No. 2. On the Relation between the Indian Pendulum Operations, and those which have been conducted elsewhere.

1. General Considerations on Pendulum Operations.
2. General Considerations on the Reduction of Pendulum Observations.
3. On a proposed Method of treatment of the Results of Pendulum Operations, with a view to facilitating the Solution of the General Problem of Local Variation.
4. Sketch of the Method of Solution from the Data as proposed in foregoing Sections.
5. Notes for a History of the Use of Invariable Pendulums.
6. On the Estimation of the Provisional Equatorial Numbers of different Pendulums.
7. Account and Explanation of the Table of Provisional Equatorial Vibration-numbers of Invariable Pendulums.
8. General Synopsis of Determinations.

Appendix No. 3. On the Theory, Use and History of the Convertible Pendulum.

1. The Convertible Pendulum as used by Kater.
2. The Theory of the Convertible Pendulum.
3. Application of the Theory in the case of Kater's and Sabine's Experiments.
4. Application of the Theory to the use of the Reversible Pendulum.
5. On the Constancy or otherwise of the Difference  $A-B$ .
6. Relation of the Subject to the Use of Invariable Pendulums.

Appendix No. 4. On the Length of the Seconds Pendulum determinable from Materials now existing.

1. Review of the Operations with Kater's Convertible Pendulum.
2. Final Comparison of Experiments with Kater's Convertible Pendulum.
3. Other Values of the Length of the Seconds Pendulum.

Appendix No. 5. A Bibliographical List of Works relating to Pendulum Operations in connection with the Problem of the Figure of the Earth.

*Vol. VI. The Principal Tringulation of the South-East Quadrilateral, including the Great Arc—Section  $18^{\circ}$  to  $24^{\circ}$ , the East Coast Series, the Calcutta and the Bider Longitudinal Series, the Jabalpur and the Biláspur Meridional Series, and the Details of their Simultaneous Reduction. Dehra Dún, 1880.\**

**Vol. VII.** *General Description of the Principal Triangulation of the North-East Quadrilateral, including the Simultaneous Reduction and the Details of five of the component Series, the North-East Longitudinal, the Budhon Meridional, the Rangir Meridional, the Amua Meridional, and the Karára Meridional. Dehra Dún, 1882.*

Appendix No. 1. The Details of the Separate Reduction of the Budhon Meridional Series, or Series J of the North-East Quadrilateral.

Appendix No. 2. Reduction of the North-East Quadrilateral. The Non-circuit Triangles and their Final Figural Adjustments.

Appendix No. 3. On the Theoretical Errors Generated Respectively in Side, Azimuth, Latitude and Longitude in a Chain of Triangles.

Appendix No. 4. On the Dispersion of the Residual Errors of a Simultaneous Reduction of Several Chains of Triangles.

**Vol. VIII.** *Details of the Principal Triangulation of eleven of the component Series of the North-East Quadrilateral, including the following Series; the Guricáni Meridional, the Gora Meridional, the Huriláong Meridional, the Chendwár Meridional, the North Parasnáth Meridional, the North Malúncha Meridional, the Calcutta Meridional, the East Calcutta Longitudinal, the Brahmaputra Meridional, the Eastern Frontier—Section 23° to 26°, and the Assam Longitudinal. Dehra Dún, 1882.*

**Vol. IX.** *Electro-Telegraphic Longitude Operations executed during the years 1875-77 and 1880-81. Dehra Dún, 1883.*

Appendix to Part I. 1. Determination of the Geodetic Elements of Longitude Stations.

2. Descriptions of Points used for Longitude Stations.

3. Comparison of Geodetic with Electro-Telegraphic Arcs of Longitude.

4. Circuit Errors of Observed Arcs of Longitude.

5. Results of Idiometer Observations made during Season 1880-81.

Appendix to Part II. 1. Situations of the Longitude Stations at Bombay, Aden and Suez.

2. Survey Operations at Aden.

3. Results of the Triangulation.

4. Right Ascensions of Clock Stars.

**Vol. X.** *Electro-Telegraphic Longitude Operations executed during the years 1881-82, 1882-83 and 1883-84. Dehra Dún, 1887.*

Appendix to Part I. 1. Determination of the Geodetic Elements of the Longitude Stations.

2. Descriptions of Stations of the Connecting Triangulation and of those at which the Longitude Observations were taken.

3. On the Errors in  $\Delta L$  caused by Armature-time and the Retardation of the Electric Current.

4. On the Rejection of some doubtful Arcs of Season 1881-82.

5. On the probable Causes of the Errors of Arc-measurements, and on the Nature of the Defects in the Transit Instruments which might produce them.

**Vol. XI.** *Astronomical Observations for Latitude made during the period 1805 to 1885, with a General Description of the Operations and Final Results. Dehra Dún, 1890.*

**Vol. XII.** *General Description of the Principal Triangulation of the Southern Trigon, including the Simultaneous Reduction, and the Details of two of the component Series, the Great Arc Meridional—Section 8° to 18°, and the Bombay Longitudinal. Dehra Dún, 1890.*

**Vol. XIII.** *Details of the Principal Triangulation of five of the component Series of the Southern Trigon, including the following Series; the South Konkan Coast, the Mangalore Meridional, the Madras Meridional and Coast, the South-East Coast, and the Madras Longitudinal. Dehra Dún, 1890.*

**Vol. XIV.** *General Description of the Principal Triangulation of the South-West Quadrilateral, including the Simultaneous Reduction and the Details of its component Series. Dehra Dún, 1890.*

*Vol. XV. Electro-Telegraphic Longitude Operations executed during the years 1885-86, 1887-88, 1889-90 and 1891-92, and the Revised Results of Arcs contained in Volumes IX and X; also the Simultaneous Reduction and the Final Results of the whole of the Operations. Dehra Dún, 1893.*

Appendix No. 1. Determination of the Geodetic Elements of the Longitude Stations.

Appendix No. 2. On Retardation (a numerical mistake was made in this appendix in the conversion of a formula from kilometres to miles: the conclusion drawn cannot therefore be upheld).

*Vol. XVI. Details of the Tidal Observations taken during the period from 1873 to 1892 and a Description of the Methods of Reduction. Dehra Dún, 1901.*

*Vol. XVII. Electro-Telegraphic Longitude Operations executed during the years 1894-95-96. The Indo-European Arcs from Karachi to Greenwich. Dehra Dún, 1901.*

Appendix No. 1. Descriptions of Points used for Longitude Stations.

Appendix No. 2. The Longitude of Madras.

*Vol. XVIII. Astronomical Observations for Latitude made during the period 1885 to 1905 and the Deduced Values of the Deflections of the Plumb-line. Dehra Dún, 1906.*

Appendix No. 1. On Deflections of the Plumb-line in India.

Appendix No. 2. Determination of the Geodetic Elements of the Latitude Stations of Bajamara, Bahak, Lambatach and Kidarkanta.

Appendix No. 3. On the (N-S) Difference exhibited by Zenith Sector No. 1.

Appendix No. 4. On the Value of the Micrometer of the Zenith Telescope.

Appendix No. 5. On the Azimuth Observations of the Great Trigonometrical Survey of India.

Appendix No. 6. A Catalogue of the Publications of the Great Trigonometrical Survey of India.

*Synopses of the Results of the Operations of the Great Trigonometrical Survey of India, comprising Descriptions, Co-ordinates, &c., of the Principal and Secondary Stations and other Fixed Points of the Several Series of Triangles. For the use of Surveyors in the field.*

*Vol. I. The Great Indus Series, or Series D of the North-West Quadrilateral. Dehra Doon, 1874.*

*Vol. II. The Great Arc—Section 24° to 30°, or Series A of the North-West Quadrilateral. Dehra Doon, 1874.*

*Vol. III. The Karachi Longitudinal Series, or Series B of the North-West Quadrilateral. Dehra Doon, 1874.*

*Vol. IV. The Gurhagarh Meridional Series, or Series F of the North-West Quadrilateral. Dehra Dún, 1875.*

*Vol. V. The Rahún Meridional Series, or Series E of the North-West Quadrilateral. Dehra Dún, 1875.*

*Vol. VI. The Jogt-Tila Meridional Series, or Series G, and the Sullej Series, or Series H of the North-West Quadrilateral. Dehra Dún, 1875.*

- Vol. VII. The North-West Himalaya Series, or Series C of the North-West Quadrilateral; and the Triangulation of the Kashmir Survey. Dehra Dún, 1879. (Vol. VII is of great use to mountaineers).*
- Vol. VIIA. The Jodhpore Meridional Series and the Eastern Sind Meridional Series of the North-West Quadrilateral. Dehra Dún, 1887.*
- Vol. VIII. The Great Arc—Section  $18^{\circ}$  to  $24^{\circ}$ , or Series A of the South-East Quadrilateral. Dehra Dún, 1878.*
- Vol. IX. The Jabalpur Meridional Series, or Series E of the South-East Quadrilateral. Dehra Dún, 1878.*
- Vol. X. The Bider Longitudinal Series, or Series D of the South-East Quadrilateral. Dehra Dún, 1880.*
- Vol. XI. The Biláspur Meridional Series, or Series F of the South-East Quadrilateral. Dehra Dún, 1880.*
- Vol. XII. The Calcutta Longitudinal Series, or Series B of the South-East Quadrilateral. Dehra Dún, 1880.*

*Spirit-Levelling Operations of the Great Trigonometrical Survey of India.*

*Heights in Sind, the Punjab, N. W. Provinces and Central India, Seasons 1858-62 :—*

From Kurrachee to Attock *via* Schwan, Shikárpur, Mithankot and Dera Gházi Khan: from Mithankot to Sironj *via* Baháwalpur, Baháwalgarh, Ferozepore, Ludhiána, Umballa, Saháranpur, Meerut, Aligarh, Agra, Dholpur and Gwalior: and from Saháranpur to Dehra Dún.

*Heights in the N. W. Provinces and Bengal, Seasons 1862-65 :—*

From Agra to Calcutta *via* Tándla, Cawnpore, Fatehpur, Allahabad, Mirzapur, Benares, Buxar, Arrah, Dinapore, Bankipore, Patna, Monghyr Bhágálpur, Nalháti, Burdwan, Pandua, Chinsura, Serampore and Howrah.

*Heights in the Punjab and N. W. Provinces, Season 1866-67, Sections I to IV :—*

From Ferozepore to Lahore and Meean Meer *via* Anarkali: from Mooltan to Khemwála *via* Muzaffargarh: from Delhi to Meerut *via* Gháziabad: and from Saháranpur to Khanna *via* Barsáwa and Umballa.

*Heights in the N. W. Provinces, Season 1867-68, Section V :—*

From Meerut to Pilibhát *via* Moradabad and Bareilly.

*Heights in the N. W. Provinces and Oudh, Season 1868-69, Section VI :—*

From Bareilly to Cawnpore *via* Sháhjahánpur, Sítapur and Lucknow.

*Heights in the N. W. Provinces and Oudh, Seasons 1868-70, Section VII :—*

From Lucknow to Dildárnagar *via* Bars Banki, Fyzabad, Basti, Gorakhpur, Azamgarh and Ghazipur.

*Heights in the N. W. Provinces and Bengal, Season 1870-71, Section VIII :—*

• From Gorakhpur to Parsurman *via* Bettiah, Segowlie, Motihari, Muzaffarpur and Darbhanga.

*Heights in Bengal, Season 1871-72, Section IX :—*

From Parsurman to Firpainti *via* Sahibganj, Purnea and Karagola Ghát: and from Purnea to Sonakhoda Base-line *via* Kishanganj.

***Heights in the Bombay Presidency, No. 1, Seasons 1874-78 :—***

From Navánár to Bombay *via* Shikárpur, Virangám, Ahmedabad, Kaira, Cambay, Baroda, Broach and Surat: from Shikárpur to Okha *via* Wawánya, Hanstal and Jorya: and from Jorya to Virangám *via* Rajkot and Wadhván.

***Heights in the Bombay Presidency and Nizam's Dominions, Nos. 2 and 3, Seasons 1877-80 :—***

From Bombay to Bidar *via* Thána, Kalyán, Lonauli, Poona, Lake Fife, Kedgaon, Diksál, Kem, Sholápur and Gulbarga: from Kedgaon to Hubli *via* Supa, Diksál, Baramati, Nira, Sátára, Kolhápur, Belgaum and Dhárwár: from Sholápur to Bijápúr *via* Jhalki and Huppargi, and from Gulbarga to Raichur *via* Yádgiri.

***Heights in the Bombay Presidency and Central India Agency, No. 4, Seasons 1877-78 and 1881-84 :—***

From Kalyán to Sironj *via* Násik, Manmád, Nándgaon, Dhulia, Mhow, Indore and Bhopal: and from Dhond to Shirsoli *via* Ahmednagar, Manmád, Nándgaon and Chálisgaon.

***Heights in the Bengal Presidency, Seasons 1881-83 and 1887-88 :—***

From False Point to Nadia *via* Kendrapara, Jajpur, Bhadrak, Balasore, Jellasore, Contai, Kukraháti, Ulubaria, Howrah, Chinsura, Tribeni and Culna: from Calcutta to Saugor Island *via* Phalta and Diamond Harbour, and from Howrah to the mouth of the Rasulpur river *via* Kidderpore, Diamond Harbour, Kukraháti, Phulbária and Kejni.

***Heights in the Madras Presidency, No. 1, Seasons 1869-85 :—***

From Madras to Kárwár *via* Arkonam, Kodúr, Cuddapah, Tadpatri, Gooty, Bellary and Hubli: from Raichur to Arkonam *via* Adoni, Gooty, Bellary, Túnikúr, Bangalore, Jalárpét and Vellore: from Jalárpét to Beypore *via* Salem, Erode, Coimbatore and Pálghát: and from Tuticorin to Cape Comorin *via* Palamcottah.

***Heights in the Madras Presidency, No. 2, Season 1885-86 :—***

From Madras to Negapatam *via* St. Thomas' Mount, Chingleput, Villupuram, Cuddalore, Porto Novo, Chidambaram, Máyavaram, Kumbakonam and Tanjore: from Tanjore to Rameswaram *via* Arantangi, Devipatnam and Ramnad: and from Ramnad to Tuticorin.

***Heights in the Madras Presidency, No. 3, Season 1886-87 :—***

From Tuticorin to Tanjore *via* Maniyáchi, Madurai, Dindigul and Trichinopoly: from Trichinopoly to Erode *via* Lálápet and Púgalúr, from Shoranur to Cochín *via* Trichúr: from Kárwár to Mormugáo, and from Agoada Fort to Agoada Fort Jetty.

***Heights in the Madras Presidency, No. 4, Season 1887-88 :—***

From Madras to Vizagapatam *via* Nellore, Guntúr, Rajahmundry and Cocanada.

***Heights in the Madras Presidency, No. 5, Season 1888-89 :—***

From Bangalore to Mangalore *via* Mágañi, Kunigal, Channaraypatna, Gráma, Hassan, Saklespur, Uppinangadi, Páni Mangalúr and Faringipet.

***Heights in the Madras Presidency, No. 6, Seasons 1888-90 :—***

From Bidar to Bézváda *via* Sadáshivpet, Pattancharu, Secunderabad, Hyderabad, Súrayapet, Munagál and Nandigáma.

***Heights in the Bombay Presidency, No. 5, Season 1889-90 :—***

From Navánár to Tatta *via* Mundra, Bhúj, Nakhtrána Mota, Mátánomadh, Lakhpat, Moghul Bhin and Sujáwal.

***Heights in the Bombay Presidency, No. 6, Season 1890-91 :—***

From Rájkot to Bhávnagar *via* Sardhár, Átkot, Bábra, Dhola and Sanosra: and from Sanosra to Port Albert Victor *via* Noghavadar, Khuntávas and Dungar.

***Heights in the Bombay Presidency, Hyderabad Assigned Districts and Central Provinces, No. 7, Seasons 1877-78, 1882-83 and 1890-91-92. Revised Edition :—***

From Nándgaon to Nágpur *via* Chálisgaon, Páchora, Bhusával, Malkapur, Shegaon, Akola, Murtazapur, Badnera, Amráoti and Wardha: and from Nágpur to Biláspur *via* Kamptee, Tumsar, Dongargarh, Nándgaon, Drug and Raipur.

***Heights in Burma, No. 1, Season 1892-93 :—***

From Rangoon to Elephant Point *via* Dala, Kóndan, Danór and Pilakat Creek: from Rangoon to Mandalay along the Sittang and Mandalay Lines of the Burma State Railway: also points about Mergui.

***Heights in the Central Provinces and Orissa, No. 8, Seasons 1891-92 and 1893-94. Revised Edition :—***

From Biláspur to Sambalpur *via* Chámpa, Sakti, Raigarh and Jhársuguda: and from Sambalpur to Kendrapára *via* Bráhmáni Turam, Binka, Soopra, Kantilo, Charchi-ka-Bánki and Cuttack.

*Heights in Karachi and its Neighbourhood, Season 1893-94 :—*

From Manora to South End Karachi Base, through Kimári and Karachi.

*Heights in Orissa and the Northern Circars, No. 9, Season 1894-95 :—*

From Cuttack to Vizagapatam *via* Khurda, Ganjam, Chatrapur and Berhampur, thence along the East Coast Railway *via* Ichchhápúram, Báruva, Mandasa Road Railway Station, Chipurupalle, Vizianagram and Waltair: and from Khurda to Puri *via* Pipili.

*Heights in Calcutta, Season 1894-95 :—*

From Her Majesty's Mint to the Standard Bench-Mark at the Mathematical Instrument Office, with an extension to the Kidderpore Tidal Station.

*Heights in the Madras Presidency, Central Provinces, Central India Agency and the United Provinces of Agra and Oudh, No. 10, Seasons 1891-92, 1894-95, 1896-97 and 1898-99 :—*

From Vizagapatam to Vizianagram, *via* Waltair, and Almauda.

From Vizianagram to Raipur, *via* Gajapatnagar, Sálúru, Potanghi, Koráput, Jeypore, Naurangapur, Umarkot and Dhamtari.

From Raipur to Biláspur, along the main line of the Bengal-Nágpur Railway.

From Biláspur to Katni, *via* Sándol and Umaria.

From Katni to Allahabad, *via* Maihar, Rewah and Mangawán.

From Katni to Sironj, *via* Damoh, Saugor, Kurai, Bina and Kurwai.

*Heights in Bengal and Assam, Seasons 1899-1902.*

From Calcutta to Dámukdia, along the Eastern Bengal State Railway.

From Dámukdia to Siliguri, *via* Nator, Nilphamari and Jalpaiguri.

From Siliguri to Sonákheda, *via* Rámganj G. T. Survey Station.

From Parbatipur to Dhubri, *via* Rangpur, along the Eastern Bengal State Railway.

From Porádaha to Faridpur, along the Eastern Bengal State Railway.

From Parbatipur to Manihári Ghat, *via* Dinajpur, Bársoi and Katihar.

From Bársoi to Kishanganj, along the Eastern Bengal State Railway.

From Katihar to Anchara Ghat, *via* Purnea and Araria.

# APPENDIX.

## No. 7.

### ON THE COMBINATION WEIGHTS EMPLOYED IN THIS VOLUME.

BY CAPTAIN H. McC. COWIE, R. E.

1. An examination of the abstracts and summaries of observations and results will show that the system of relative combination weights described in Section 7, Chapter II has not always been adhered to and that, in many cases, the reasons for departure from this system are not at once evident. Some explanation, then, seems called for with an account of the development of the system now adopted.

2. Before the year 1899, in combining the individual values to obtain the final co-latitude, no system of relative weights was used. That is to say, every value, whether dependent on one or on several observations, or whether the pair were independent or entangled with others, was allotted equal weight. By this procedure, values which depended on several observations of the same pair of stars were relatively under-weighted, while those derived from single observations and from entangled pairs were over-weighted.

3. In 1899, for the first time, a system of relative weights was introduced. This was purely an arbitrary one, having no theoretical basis. To the result from each single observation of an independent pair of stars was allotted a weight of 0.5. Two observations raised the weight to 1.0; three to 1.5 and so on. Each component value of a double pair, deduced from a single set of observations, was given a weight of 0.5. Values dependent on two or on three observations of entangled pairs received weights of 0.75. Under this system, it is evident, the values given by single observations of independent pairs were relatively under-weighted, while results derived from repeated observations of independent pairs and all values from entangled pairs were over-weighted.

4. In 1901, the system described in Chapter II was first introduced, though for this and the following year, the numerical values of the relative weights differed slightly from those given on page (24), in consequence of the derivation of the values of the quantities  $\eta$  and  $\epsilon$  from the season's work. This investigation entailed somewhat laborious computations and as each successive season's results showed that the values of  $\eta$  and  $\epsilon$  did not differ materially from  $\pm 0''.20$  and  $\pm 0''.30$  respectively, it was considered that an annual examination of results was unnecessary and that the adoption of the above mentioned values for  $\eta$  and  $\epsilon$  was fully justified. The table of the relative weights given on page (24), computed with these data, has been in use from the season 1902-03.

5. Such, from time to time, have been the various methods of procedure followed in combining the individual values of the co-latitude. In the compilation of this volume, however, it has been thought advisable for the sake of uniformity, to reconsider all observations made prior to the season 1898-99 and to apply to the individual observations the most recent system of relative weights, and so to deduce final values comparable with the work of later years. But as the changes in the final values of co-latitude, consequent on the alteration of the combination weights, were not of a magnitude to justify the labour of recomputation, the results of the four seasons 1898-99 to 1901-02 have not been recomputed and in the abstracts of observations given in this book for the years 1898-1902, the system of weights employed is that originally adopted for the season's work.

6. In many of the abstracts, again, the weights applied will be seen to conform neither to the system of 1901 nor to that of 1903, and the reasons for the discrepancies not being at once evident, a note of explanation is necessary. In the concluding paras of Section 6, Chapter II attention is drawn to the importance of balancing the sums of positive and negative micrometer corrections, for the purpose of eliminating errors due to a faulty value of a revolution of the micrometer screw. It is generally possible to contrive an approximate balance of positive and negative differences at the time of drawing up the programme of work. The desirability of balancing, however, was not recognized till the year 1891 and the micrometer differences in observations taken prior to this date had to be subsequently balanced by the arbitrary alteration of weights. Even when a programme of stars has been so framed as to produce a perfect balance, the latter will frequently be disturbed by the accidental missing of stars or by the interference of clouds or by the rejection of certain individual values of co-latitude, on account of gross errors of observation. Measures have then to be taken to readjust the balance of corrections. This may be done in two ways:

(1) By rejecting arbitrarily one or more observations.

(2) By slightly altering the combination weights.

Both methods are the same in principle. To reject an observation is to give it a weight of 0.0. By the first method, a few results are given no weight at all; by the second, the weights of a greater number of results are altered by smaller amounts. In some instances the first method has been followed, in others the second, and it is to this arbitrary alteration of weights that the discrepancies referred to at the beginning of this paragraph are due.

7. The case of entangled pairs has now to be considered. There will be found in the abstracts of this volume several instances in which the weights employed are not theoretically correct, but of which the errors cannot be attributed to any of the causes discussed above. These instances will be seen to occur wherever a number of stars have been observed with the same instrumental setting and where several individual values of co-latitude have been derived from the same observations. These values are, in consequence, not independent. The commonest case is that in which observations to two stars of one aspect are combined with observations to one star of the other aspect and two values of co-latitude deduced from the three observations.

The case of a double pair has been considered on page (24), where the appropriate weights have been determined. But though a double pair is of commonest occurrence, the abstracts contain many instances of a more complicated kind. Such as, for example, when four stars are, perhaps, combined to give three values of co-latitude, or five stars to give four values. On some occasions four stars of one aspect have been combined with but one of the other; and there are cases of three stars of one aspect being combined with two of the other. All these various cases should have been treated individually in order to obtain the appropriate weights. This, however, has not been done, as it was not considered necessary to introduce refinements whose effect on the final co-latitude was negligible. The procedure has been to treat each component as if it were one of a double pair, and to weight the individual results accordingly.

8. In addition to the cases already dealt with, there are in the abstracts a few instances of a weight having been arbitrarily altered by the observer; the observation in his opinion not meriting full weight.

9. In Section 7, Chapter II, the case of three stars being combined to form two entangled pairs has been investigated and the appropriate weights determined. As has been already stated, this, the double, is the most common form of entangled pairs. Of recent years observers have endeavoured to reduce and if possible to eliminate intricate entanglements; but the abstracts of earlier work show many combinations of great complexity. Following the procedure of Section 7, I have determined the relative combination weights for a few specimen cases. These are given below:

Case (a) in which a star transits so close to the zenith that it may be observed in both telescopic positions with the same instrumental setting and where  $c = \Delta + \frac{Z_1 - Z_2}{2}$ , where  $Z_1 - Z_2$  is the difference of the zenith distances measured in the two positions of the instrument and  $c$  the co-latitude.

Instances of this will be found in

Station	112	pair number	27
"	117	" "	28, 33
"	131	" "	40
"	135	" "	5

If the p. e. of a single declination be  $\pm 0''.8$  and the p. e. of observation in a single determination of co-latitude be  $\pm 0''.8$

$$(p. e.)^2 \text{ of } c = (0.8)^2 + (0.8)^2 \\ = 0.18.$$

Where a pair of stars is observed one north, the other south of the zenith

$$c = \frac{\Delta_N + \Delta_s}{2} + \frac{Z_N - Z_s}{2}$$

$$\text{and } (p. e.)^2 \text{ of } c = (0.2)^2 + (0.3)^2 = 0.13.$$

Hence if  $w$  be the weight appropriate to a value for the co-latitude deduced from observations to one zenith star, and  $W$ , the weight of a result by a pair of stars,

$$\frac{w}{W} = \frac{0.13}{0.18} = 0.7$$

$$\text{If } W = 1.0 \quad w = 0.7.$$

The mean result from two sets of observations to a zenith star should then be given a weight  $w = 0.7$ . The result by one set of observations should receive a weight

$$w = 0.7 \times 0.7 = 0.5.$$

Case (b) in which two north stars and two south stars are observed with the same instrumental setting; for example

Station	142	pairs	22	to	25
„	145	„	8	„	11
„	158	„	8	„	11

Utilizing the symbols  $p$  and  $q$  of Section 7, the combinations we may form are

$$\begin{aligned} c_1 &= p_1 + q_1 \\ c_2 &= p_1 + q_2 \\ c_3 &= p_2 + q_1 \\ c_4 &= p_2 + q_2 \end{aligned}$$

of which, as is at once evident, two are redundant. For the mean value of co-latitude from the four combinations above is

$$c = \frac{1}{2} [p_1 + q_1 + p_2 + q_2]$$

which is the mean result from the two combinations

$$\begin{aligned} c_1 &= p_1 + q_1 \\ c_4 &= p_2 + q_2 \end{aligned}$$

It is, thus, a mistake to introduce the other two combinations

$$\begin{aligned} &p_1 + q_2 \\ \text{and} &p_2 + q_1 \end{aligned}$$

In determining the weight of the mean result, we may consider the  $p. e.$ 's of  $p_1, p_2, q_1, q_2$  each equal to  $e$ ; then

$$(p. e.)^2 \text{ of } c = 4\left(\frac{e}{2}\right)^2 = e^2.$$

Again the  $(p. e.)^2$  of the result by a single pair =  $2e^2$ .

Therefore if  $W$  be the weight of the result from a single pair and  $w$  the weight to be given to  $c$

$$\frac{w}{W} = \frac{2e^2}{e^2} = 2$$

from which, if  $W = 1 \quad w = 2$

Hence, if all four stars be twice observed and the four possible combinations be formed from the observations, a weight of 0.5 should be allotted to each component. Had the observations been combined to form the two independent pairs

$$\begin{aligned} &p_1 + q_1 \\ &p_2 + q_2 \end{aligned}$$

a weight of 1.0 would have accrued to the result from each, under system of Chapter II, the aggregate weight of the mean co-latitude deduced from the observations being as before 2.0.

The two combinations  $p_1 + q_2$  and  $p_2 + q_1$  are thus superfluous, they influence neither the final mean result nor the aggregate weight of that result.

When several stars have been observed with the same instrumental setting, it is essential that the observations should be so combined as to give the most probable value to the mean result.

In the case of the four observations considered above, two courses are possible: either both the superfluous combinations should be rejected or both should be included. It would be incorrect to reject one only. For if, for example, we formed the three combinations

$$c_1 = p_1 + q_1$$

$$c_2 = p_1 + q_2$$

$$c_4 = p_2 + q_2$$

the mean result would be

$$c' = \frac{1}{3} [2p_1 + q_1 + p_2 + 2q_2]$$

instead of

$$c = \frac{1}{4} [p_1 + q_1 + p_2 + q_2],$$

the most probable mean value resulting from the four observations.

The aggregate weight of  $c'$  can be shown to be 1.8, the introduction of the combination

$$c_2 = p_1 + q_2$$

actually diminishing the aggregate weight by 0.2; a clear proof that the data at our disposal has not been combined to give the most probable mean result.

The following table shows the combination weights determined for a few cases:—

TABLE I.

Number of Stars		No. of entangled pairs formed	Weight for each entangled pair		Examples
Of one Aspect	Of other Aspect		Observed once	Observed twice	
2	3	4	0.4	0.6	Station 155 pairs 11 and 14
4	1	4	0.3	0.4	„ 134 „ 18 and 21
5	1	5	0.2	0.3	... ..
4	2	5	0.3	0.4	... ..

10. Table II gives a summary of all cases, in which the weights allotted in this volume differ from those derived under the system described in Chapter II: it also shows the effect on the final co-latitude of the adoption of arbitrary and un-systematic weights.

The differences,  $M' - M$ , must not however be regarded as errors. In all cases in which the substitution of systematic for arbitrary weights has disturbed the balance of micrometer differences, the final result has been rendered less reliable and the value of  $M'$  less trustworthy than that of  $M$ .

TABLE II.

Reference Number of Station	Number of Values whose weights have been altered	Results as given in the Abstracts of this volume		Results that would have obtained if weights had been employed in accordance with system of Chapter II		Difference $M' - M$	Reason why allotted weights differ from those of the system of Chapter II

11. Table III gives details, relating to observations by the Talcott method with the Zenith Sector No. 1 and with the Zenith Telescope. This table shows the *p. e.* and the aggregate weight,  $\Sigma P$ , of the final values of the co-latitude. From which two quantities, the *p. e.* of a result, having unit weight, has been deduced. This latter is exhibited in the last column of the Table.

TABLE III.—Details relating to observations by the Talcott Method.

LATITUDE OBSERVATIONS WITH THE ZENITH TELESCOPE

Survey of Santa Theresa, October, May 1906

PLATE II

SAFARIING CAMP ON THE RIVER IN THE MOUNTAINS

Source of the Nile, Africa, July 1901

PLATE III

• CHART  
• to illustrate the positions  
• of the  
• Latitude stations of India

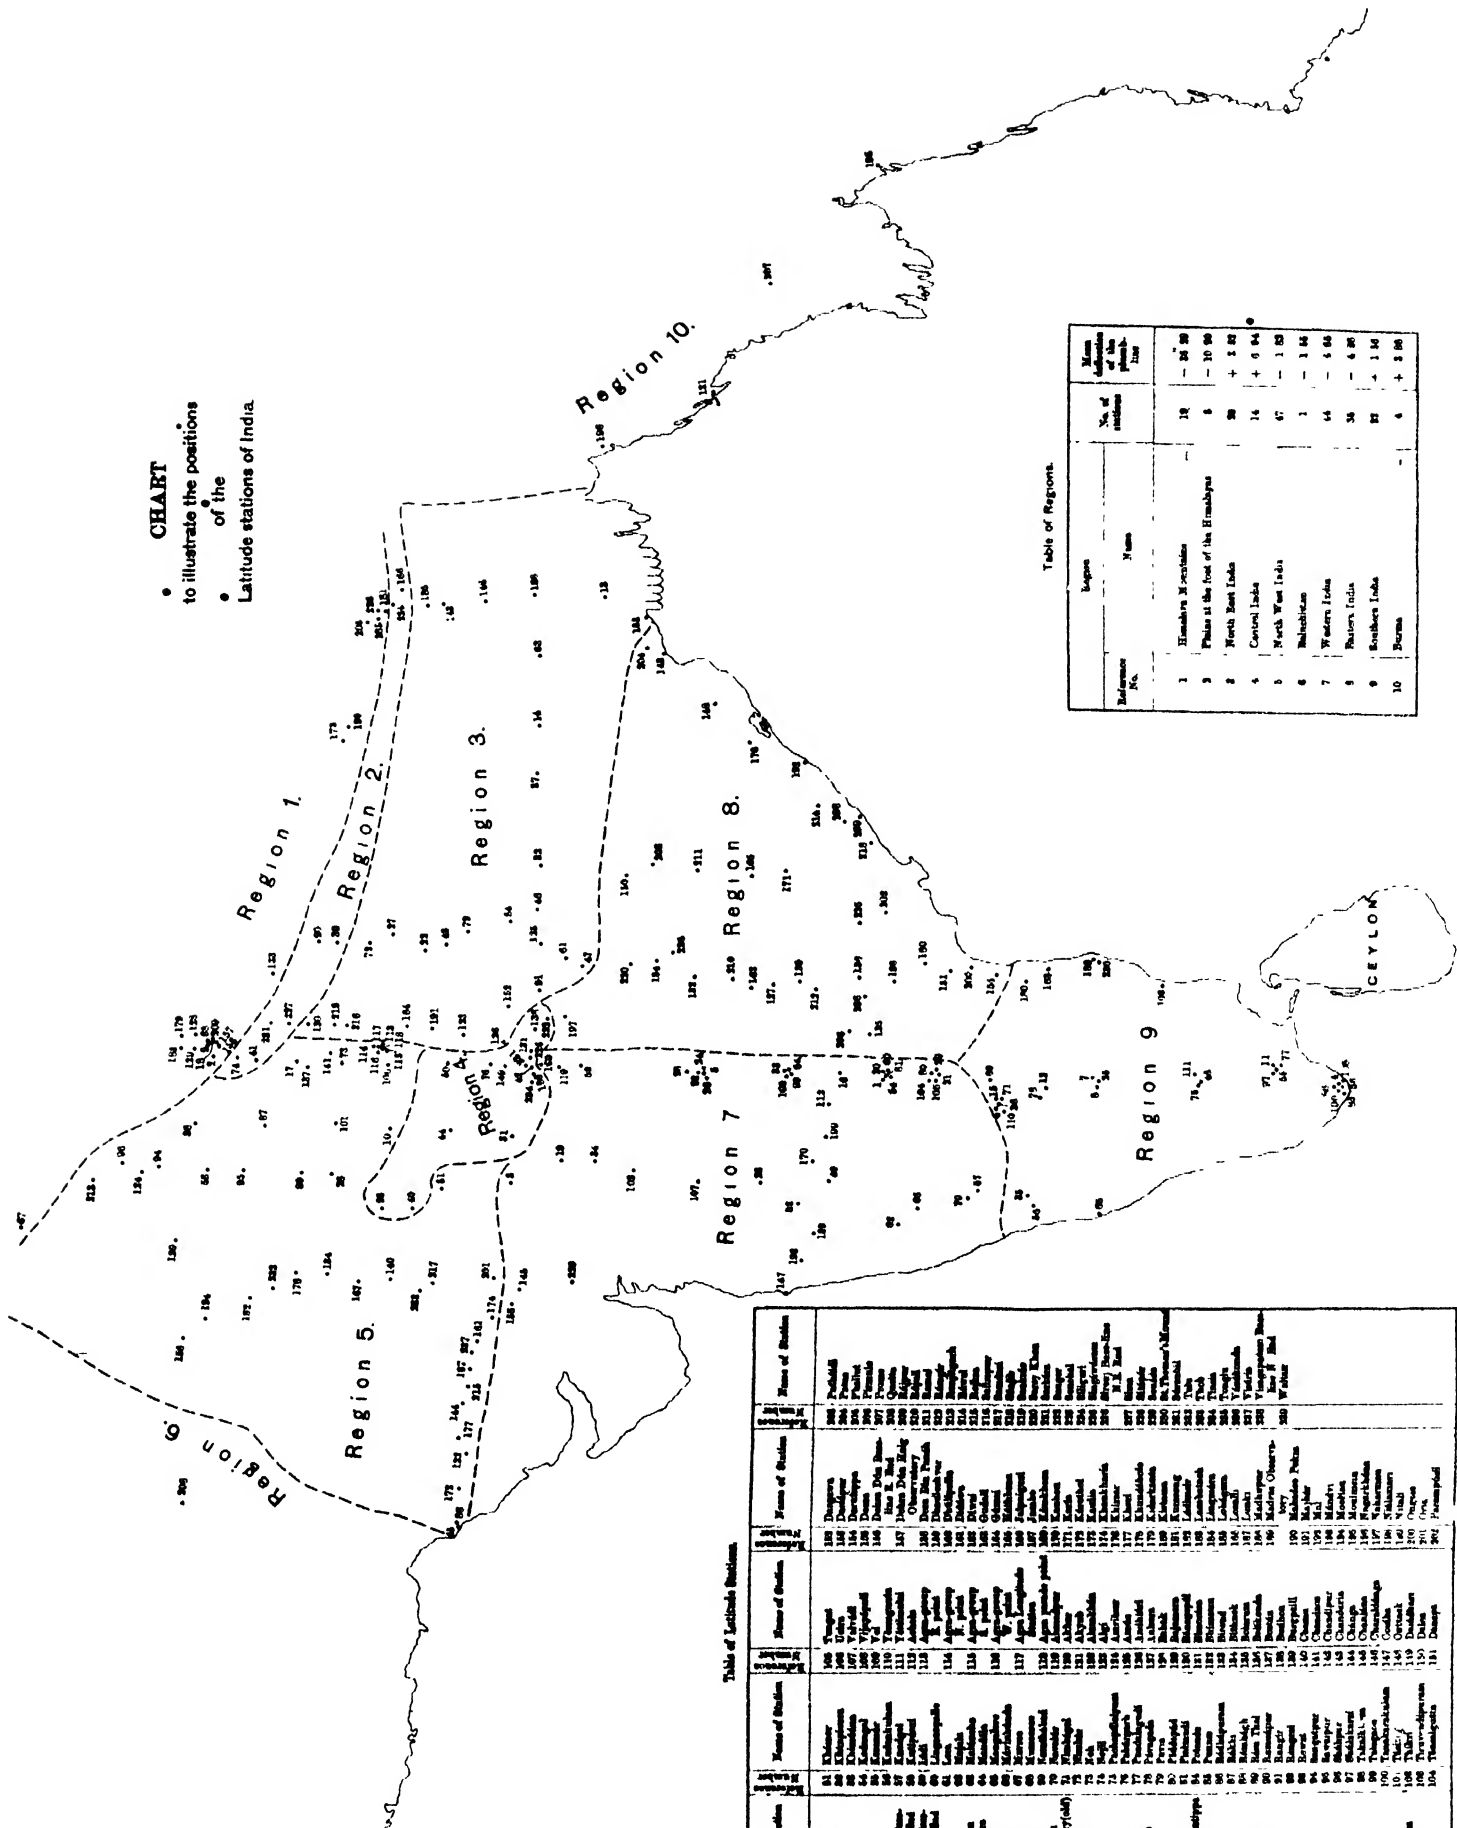

Table of Regions.

Region No.	Region Name	No. of stations	Mean altitude of the place, feet
1	Himalayas & vicinity	18	- 25 50
2	Plain at the foot of the Himalayas	5	- 10 00
3	North West India	20	+ 2 00
4	Central India	15	+ 0 00
5	North West India	47	- 1 00
6	Malabar	1	- 1 00
7	Western India	14	- 0 00
8	Eastern India	35	- 0 00
9	Southern India	27	- 1 00
10	Sumatra	4	+ 2 00

Station No.	Name of Station	Longitude	Name of Station	Longitude	Name of Station	Longitude	Name of Station	Longitude	Name of Station	Longitude
